

Modifying the R-390A for SSB

June 1963 by Captain Paul H. Lee, USN W3JHR

The R-390A receiver requires an outboard converter unit for satisfactory SSB reception. The simple modification outlined below provides a product detector combined with the BFO circuit at a low cost.

As originally designed, the R-390A HF receiver is usable, to a certain extent, for SSB reception without an external SSB converter, but it performs very poorly because the AM diode detector contributes considerable distortion. The relative levels of signal vs BFO injection voltage are not correct for proper SSB detection. The levels can be made more optimum by reduction of the RF gain, but then the AGC action is lost and weak signals are reduced so much that they are overlooked or unheard. The R-390A was designed to feed an IF signal to an external SSB converter. However, by a simple and inexpensive modification of the internal BFO stage to a product detector, the R-390A can be made to perform as an excellent SSB receiver by itself, with no external converter being required for SSB (For ISB, however, an external converter is required, in the form of 2 CV-591s or 1 CV-157) The modification is very simple, inexpensive, and does not require any contract procurement action, nor does it involve any proprietary designs. The modification: requires less than 2 hours work by one man. The parts required for the conversion are few and simple, and cost less than ten dollars.

Conversion Procedure

The conversion is performed as follows:

- Remove the BFO B+ wires from the BFO ON-OFF switch S101. Remove and discard S101, but retain the knob.
- Cut three 20" lengths of single conductor shielded microphone cable.\
- From one end of each of these three pieces, remove the outer plastic jacket and carefully unravel 1" of the shield braid and form a 1" pigtail lead. Twist the 3 pigtails together and solder them together, being careful not to melt the plastic insulation on the inner conductor of each piece of wire.
- Take the new switch, a 2 pole two to six position unit, (only 2 of the 6 positions are used) for S101, and connect these three shielded leads to it to form the audio changeover circuit. See schematic below. Under the head of the machine screw holding one side of the switch wafer to the switch frame install a small soldering lug. Solder the pigtail to it, to ground (at this end only) the individual shield braids of the 3 audio wires.
- Insert the free ends of the 3 wires through the opening at the edge of the IF shelf, pull them upward above the IF chassis, and mount the new switch in the vacant S101 hole in the front panel. Replace the knob. Connect the BFO B+ wires to the

other pole of the switch. The BFO B+ is to be on in the BFO ON position, which will become the SSB position of S101. See the schematic below.

- Unplug all plugs from the IF subchassis, mechanically disconnect the 2 control shafts, and remove the IF subchassis from the receiver.
- Carefully remove the cable clamp and cover from multi-conductor plug P112, slipping it back out of the way. There is one spare pin, P112-1 Remove the wire from pin P112-7 and leave it hanging.
- Twist the 3 shielded wires installed in step 2 into a 3 conductor cable, above the chassis. Wrap with plastic tape at 4" intervals. Cut this cable to the required length to reach plug P112 leaving sufficient slack for clearance over the IF chassis and tubes. Strip back 1" of outer plastic jacket and shield braid on each of the 3 wires. Run the 3 wires through the cable clamp and plug cover.
- Connect the shielded wire from the SSB (BFO ON) audio terminal of S101 to pin P112-1. Use an insulating sleeve for protection, as is done for the other wires on the plug.
- Connect the shielded wire from the AM (BFO OFF) audio terminal of S101 to pin P112-7. Use an insulating sleeve as in step 8.
- Slip an insulating sleeve over the free end of the remaining wire, which should be the one connected to the rotary "arm" of S101. This is the "audio input" lead. Solder it to the free end of the wire left hanging in step 6. Slip the insulating sleeve down over the bare connection. Carefully replace the cover and cable clamp on P112. Tape these 3 wires to the existing cable just outside the clamp.
- Turning the IF chassis over, carefully remove the bellows coupling on the BFO PITCH control shaft. Remove the shaft by loosening the panel bearing. This step clears some working space around the socket of V505 BFO tube.
- Remove and discard the V505 6BA6, BFO tube.
- Remove the ground (and all wires) from pin 2 of V505. This may involve shifting several ground leads to other ground tie points on the chassis.
- Move the existing lead from V505 pin 7 to pin 2. (This is the cathode tap on the BFO coil Z502).
- In the following steps, be sure to leave room for replacing the bellows shaft coupling.
- Connect the 11K $\frac{1}{2}$ watt resistor from V505 pin 7 to ground.
- Remove and discard C535.

- Connect the 2.7K 1 watt resistor in parallel with the existing screen dropping resistor R529.
- Connect the 5 mmf capacitor between V505 pin 7 and V506B pin 6. This is the IF coupling into the injection grid of the 6BE6 product detector.
- With a pair of small metal shears cut a 90° V-shaped notch in the lower edge of the interstage partition near the rear of the BFO coil Z502. Cover the edges of this slot with short pieces of plastic tape.
- Mount the 200 mmf and 500 mmf capacitors on the grounded center post of the V506 socket, letting them be supported in space by their own ground leads (about 1" long).
- Connect the 56,000 ohm 1/2 watt resistor between the free ends of the 200 and 500 mmf capacitors.
- Connect the 0.02 mf capacitor from V505 pin 5 to the 500 mmf end of the 56,000 ohm resistor.
- Use 12" of the shielded microphone cable for the SSB audio lead.
- Remove 1" of the plastic jacket from one end, and make a 1" braid pigtail on this end: Slip a 7/8" insulating sleeve over the pigtail and ground the pigtail to the center ground post of V506 socket. Connect the center conductor to the 200 mmf end of the 56,000 ohm resistor.
- Lay the shielded wire in the V-shaped slot in the interstage partition, and tape it in position with a 2" length of plastic tape. Cut the wire to length to reach pin J512-1 of the rear cable socket.
- This is the unused pin. It mates with Pin P112-1 of the cable plug. Strip back 1/2" of the plastic jacket and braid from this end of the shielded wire. Connect the wire to pin J512-1, using an insulating sleeve over it for protection.
- Carefully replace the BFO shaft and bellows coupling removed in step 11. Make sure the coupling does not accidentally ground any components or wiring.
- Replace the IF subchassis in the receiver. Insert all the plugs removed in step 5. Reconnect the 2 control shafts and replace their front panel knobs. Make sure the BANDWIDTH knob is properly positioned on the shaft.
- Plug in the 6BE6 tube in socket V505. Turn on the receiver.
- Leave the antenna disconnected.

- With the b.f.o. switch S101 in the ON (SSB) position, a hissing sound will be heard in the loudspeaker. With the bandwidth switch in the 1 KC position, rotate the BFO PITCH knob. The pitch of the hissing sound will vary from high to low and back to high again, as the oscillator portion of the 6BE6 is tuned through the center of the receiver IF bandpass. Set the BFO PITCH control for the lowest pitch of the hiss. Without rotating the shaft, loosen the knob set screw, and set the knob pointer to "0". The pitch of the hiss should now rise equally at the --1 and +1 positions of the control.
- Set the BANDWIDTH knob at 2 KC, and at 4 KC. In each case, the pitch of the hiss will be lowest at the "0" position of the BFO PITCH control, rising an equal amount on each side (-1, +1 or -2, +2).
- The original AGC action is not satisfactory for SSB voice reception.
- It is too fast in the FAST position and produces a "pumping" action. In the MED position it is a bit too slow for fast voice break-in operation.
- From the unused terminal 10 of the AGC switch S107 (FAST position) connect the 1.0 mf capacitor to ground. See the top figure on this page. This may be done most conveniently by soldering one capacitor lead directly to the switch lug behind the front panel, and connecting the other lead to a ground lug placed under the RF section top cover screw just back of the center of the front panel. This places 1.0 mf in series to ground with capacitor C551 (2.0 mf) in the FAST position, making a total of 0.66 mf across C548 in the grid circuit of V506A the AGC time constant tube. The resulting time constant has been found by experimental use to be quite satisfactory, producing SSB voice signals which are pleasing to the ear to copy. For multiplex or composite waveforms of essentially constant amplitude, the MED or SLOW AGC may also be used, as desired. the MED or SLOW AGC may also be used, as desired.
- The receiver is now ready to operate. Connect the antenna.
- With the AGC switch set at FAST, and BFO ON, tune in an SSB signal in the 14 MC amateur band, with the BFO PITCH control set at -2, and the BANDWIDTH control at 4 KC. It should sound very pure, clean, and undistorted (assuming the station's emission is clean and undistorted). The BANDWIDTH control may be set at 2 KC for interference reduction, with the BFO PITCH set at -1 in this case.
- Shift frequency to the 7 or 3.9 MC amateur bands. Tune in signals here in the same way, but with the BFO PITCH set on the opposite (+) side of "0".
- Most 14 MC amateur emissions are upper sideband, whereas those on 3.9 and 7 MC are usually lower sideband. Note that the BFO PITCH must be set to the opposite side of the carrier ("0") for reception of the desired sideband (- for USB, + for LSB). When you do this, you are in effect placing the locally injected carrier from the oscillator portion of the 6BE6 in the proper position for demodulation of

the SSB signal and for positioning the signal correctly within the receiver passband. CW may also be received with the BFO switch on (SSB position), using BFO PITCH and BANDWIDTH controls as desired. For AM, the BFO switch is OFF, unless AM reception in the SSB mode is desired in which case it is ON.

The conversion is now completed, and the R-390A may now be used for SSB with no external converter.

This detailed information applies only to the R-390A. A similar conversion can be worked out for the R-390 or any other good superheterodyne receiver. It has been used with success in several Collins R-388 (51J)1 receivers and AR-88 receivers by the writer. In the R-388, the oscillator portion of the 6BE6 has been crystal controlled, with 3 crystals (1 for USB, one for exact IF, and 1 for LSB) selected by a switch in place of the BFO PITCH control. Crystal control is not so practical in the R-390A because of the selectable IF bandpass. A multiplicity of crystals would be required.

1 Lee, P. H. Cdr., "The Single Tube Product Detector," CQ, April 1961, p.50.

R390A Modification to Improve SSB Performance

The major reason for poor SSB performance of the R390A is inadequate AGC, which fails to keep signal strength at the detector below the level of the BFO, thus causing severe distortion. The changes listed below increase AGC action and greatly shorten the attack time while lengthening the release time. BFO injection is also increased slightly. The end result is greatly reduced distortion on SSB.

The changes accomplish the following:

1. Change the AGC rectifier to a voltage doubler and increase AGC amplifier gain.
2. Change AGC time constant resistors for faster attack, slower release
3. Remove AGC voltage from the suppressor grid of the AGC IF amplifier

The following should take about 40 minutes:

1. Remove IF subchassis.
2. Install a diode such as 1N60 across R546 (180K), cathode to tube socket.
3. Remove R546 (180K) and R545 (100K).
4. Replace R547 (220K) with a 10K 1/2 watt resistor.

5. Replace R544 (2.7M) with a 4.7M 1/2 watt resistor.
6. Move C547 (0.1uf) from its present location (chassis ground and pin 2 of V508) to a new location between chassis ground and the tie point to which the anode end of the new diode is connected. This changes nothing electrically but is required for the next step.
7. Locate the jumper wire running from pin 2 of V508 to the tie point mentioned above. Cut it at the tie point and reconnect the free end to pin 7 of V508.
8. Examine R504. If it is not 560 ohms, change it to that value (This is a production change.)
9. Replace the IF subchassis, realign the BANDWIDTH and BFO PITCH knobs.
10. Examine the shield can of Z503. If the top has no alignment hole, remove the can, drill or punch a 1/4 inch hole in the center of the top, and replace the can.
11. Connect a VOM or VTVM to read AGC voltage (negative voltage at terminals 3 and 4 of TB102 on the rear panel).
12. Replace AGC amplifier V508 (6BA6) with a 6CB6.
13. Set receiver to 1 kc bandwidth, tune in a calibrate signal, and adjust the slug in Z503 for maximum AGC voltage. Do not adjust the other IF transformers.
14. Connect a VOM or VTVM to read detector diode voltage (negative voltage at terminals 14 and 15 of TB103 on the rear panel).
15. Turn on BFO. Note detector voltage. Replace V505 (6BA6) with a 6AU6, trying several 6AU6 tubes if available. Select tube with highest reading.

As a final adjustment, the GAIN ADJ control on the IF subchassis should be set for the least usable gain. Too high a setting increases distortion and produces high AGC voltage, which, applied to the front end of the receiver, decreases the signal-to-noise ratio. NNN0EDX VA

Dallas Lankford SSB AGC mod (HSN 23)

Date: Sat, 16 Jan 1999 13:58:50 EST
From: DCrespy@aol.com
Subject: [R-390] R-390A, Real simple SSB

This worked so well, I feel like I need to tell some other users about it!!

I did the Dallas Lankford SSB AGC mod (HSN 23).. the simple one (just two

diodes, no parts removed).. last night. Really unbelievable result. AGC actually works on SSB. I can copy all SSB signals with full RF gain, with minimum distortion. The AGC action is evident, that is: as the RF gain is reduced, the signal audio level remains constant until the carrier meter reads '0', then it begins to drop off.

Besides fast attack, slow decay, the mod appears to 'more aggressively' reduce gain with AGC action (per Lankford, each signal produces more AGC voltage than before). Has anyone measured Dynamic Range with this mod. It seems like it would be improved?

Its just two 1n4148 diodes, one in parallel with R-547 (anode to ..diode 'points away from' pin 2 V-506), one in parallel with R-546 (cathode to.. 'points toward' pin 1 V-509).

(I also tried the increased BFO injection mod that Lankford suggests in a later article. I was surprised and disappointed that the added BFO injection did fool the AGC, further reducing gain. I undid the mod and left BFO injection 'stock'.)

I would like to hear from others who have tried this or similar mods.

For the R-390 list: this looks to me like a much better way to spend your time and effort than on 3TF7 mods!

>"real thing". :)

Welllll... I looked into one of those little epoxy-encased modules a while back. Looks to me like it is not much more than audio-derived AGC. I never did get any technical information out of the maker, but I did my version of the same mod to one of my 390A's to see how it would work, and amazingly I got about the same results that were claimed for the little module for about \$1 worth of parts (I see flames in my future for that remark....) What I did was bridge-rectify the "line out" audio, filter it, and apply the neg voltage to the AGC connector on back. I will get back with actual parts values if anyone is interested. The mod works well, is attached to the radio only with spade lugs, and makes SSB liveable. Now the CV-591 made it more liveable on R390A #2, but this cheap mod does a pretty good job, and is adjustable via the line audio pot.

Subject: [R-390] RE: usb/lb Tune Aid

The thing from Radiofinder is not worth much. The basic idea is a bridge rectifier connected to the audio, and that is filtered and run into the AGC. You use the line audio control to control how much audio goes into it, and listen on the local audio. So it gets you some audio-derived AGC which is a good way to get AGC for SSB reception; and it knocks down the RF gain some so that the BFO has a chance of demodulating the SSB signal with less distortion. But it doesn't work very well; the best thing that can be said for it is that it requires no internal mods to the receiver.

Subject: [R-390] SSB adapter

The recent thread concerning the Radio Finder SSB adapter is very interesting but not new. This device, in various forms and under various labels, has been around at least since 1985 when venerable Hollow State Newsletter editor at that time, Dallas Lankford, purchased one and wrote a review - not favorable - in HSN #10. The most recent re-appearance in HSN was in #41 (Spring 1997) in an article by Reinhard Wieschoff-van Rijn who purchased one from an ad in ER. He boiled it down to dissolve the potting material and found essentially what has been described as a full-wave bridge rectifier (AC leads connected across the line output terminals on the rear terminal board - 10 and 13) and filtered (6 microfarad-600V). A schematic is included in the article. His conclusion - not very useful and could be built with junkbox parts or all new for a very few bucks.

Subject: [R-390] R390A SSB Thoughts

There has been a lot of activity about putting the R390 series receiver on SSB. I am constantly approached by those who would have me modify the receiver to work on SSB during a restoration. I do not modify the receiver for SSB no do I recommend it. Here is my opinion why it should be left alone.

The R390(A) were designed before the general acceptance of SSB. The receiver was not designed to receive SSB in any manner. There are adaptors such as the CV-591 which will allow the '390 to detect SSB but they don't work all that well.

The R390 family of receivers were designed to receive AM and CW. Why not leave it at that? If your needs dictate a receiver optimized for SSB, there are plenty around. In fact, there are more of those than any optimized for AM.

From: Dave Rickmers <rickets@...>
Subject: Re: [R-390] R390A SSB Thoughts

It is my experience that my stock R-390A works extremely well for SSB monitoring. The receiver must be properly "tweaked" and stable. RF gain should be backed way off. AF gain turned up. The BFO should be set at 1.5-2 kHz. 2 kHz filter. With this configuration, background noise is way down but actual communications are generally loud and clear. If the VFO is properly aligned, it is quite possible to tune the receiver to a frequency and wait for a communication, and have that communication sound very close to natural (very slight readjustment of the KC control may be required). The key here is to not have so much signal (RF Gain) that the BFO cannot produce a enough "carrier". Back-off the RF, turn up the AF. BTW, I use 5574 usb for testing purposes, as comms are pretty regular on this frequency, here on the west coast of North America.

As a historical matter, I agree that hacking up a nice 390/390A is not a good thing to do (although hacking up a "beater" doesn't bother me). But the 390 has many virtues that some of us would like to bring to our SSB reception. Also, although I love BAs there is a limit to how many I want to deal with for practical listening. One do-everything radio is an appealing notion.

My solution (still conceptual -- I haven't built it yet) is to use the IF output and some minimal mods to the radio. I'll add a BFO output, so the 390/A's BFO control will still work as expected (could either drill the rear panel, hang a pigtail out, or use one of the antenna connectors). The external box will be a product detector, an AGC detector, and maybe one or more notch filters. Those who like fixed USB/LSB BFOs could add xtal oscillators and dispense with the BFO output on the 390/A. The AGC circuit in the 390/A will need to be modified to accept the external AGC gracefully, but since I'm not all that fond of the 390A AGC even for AM, I would modify it anyway.

The R390 series are great RF/IF decks. Why not make them do what you need, as long as you're not defacing a historical artifact?

A very simple but effective and not too invasive mod it to increase the BFO injection level to the detector to make it an exhalted BFO scheme. This merely requires the paralleling of the coupling cap with an additional mica. I forget the value right now, but it was documented by Dallas Lankford (did I spell that correctly).

Around 1980 I modified a R390A with a kit I got from a ham in MARS. It made SSB a dream and eliminated the AGC distortion. I've looked but so far have not found the paperwork for it. It involved using a free triode section and adding a diode. Sadly, I sold that set a while ago. Has anyone heard of this before?

Subject: [R-390] R-390A & SSB

It might be of interest to you guys that think the 390s were only designed for AM/ CW is that several of the later manuals show how to interconnect SSB adapters, but more interestingly, some very late radios might have had product detectors installed at the factory with a mode switch that included USB and LSB. A ham in Italy has one of these very very rare R-390As. I saw a picture of the front panel once, and sure enough, there were extra positions and markings!

The last r-390s were built in 1984 by Fowler Industries on special order for the Pentagon... as I recall only five were made in that production "run", so the cost per radio was rather high ...\$ 34,000 or \$38,000 EACH. if I recall correctly. Maybe these sets had the SSB upgrade installed?

If anyone could get hold of a manual for this series, it might contain some interesting upgrade ideas.

Subject: Re: [R-390] R390A SSB Thoughts

Don: I have been reading each of the items and I agree with you; there is absolutely no reason that the R390A, if can be improved to do a specific thing, shouldn't be improved!!! The US military had the radio built to do many things--and it did it well over it's fabulous history. However, Hams and DXers have also used it for years and have adapted it to do many things. For example--who in their right mind, while living in the South, would leave the PTO heaters connected? Do YOU need that extra heat to heat up the shack? I think not...but that may not be the case if you were in Nome Alaska....Same thing for SSB...Remember, there IS an IF output in the back of the receiver--it's not there for show. Now if there was a system that would take an 455 kHz IF, and give you multiple audio detection options.....There just happens to be something built by Sherwood Engineering that does just this..So it is not outlandish to consider SSB operations with the R390A...and you don't have to modify the receiver at all in this case! The same thing can be said about the AGC..Incidentally, why doesn't someone describe some of the AGC mods to make the audio better? After all, that's part of what this group is all about..... I have appreciated each and every one of the entries over the past week or so...Keep up the good participation...That's what makes this group so special!

I have one such radio and it does not work any better than just turning the BFO on. I have heard from those who have tried the CV-157's et al that the performance is not all that great. I have used a Sherwood SE-3 III with mine. Although the AM audio recovery is incredible, the SSB performance is not all that great.

The Fowler R390A's did not have SSB installed. I know of a fellow who has one. And yes, they did make just 5.

From: FSWF37A@... (JAMES T BRANNIGAN)
Subject: [R-390] r390a SSB thoughts

The CV-591/URR is also known as the MSR-1. The MSR-4 or 5 had a AGC take off to control the receiver. I think it was the GSB-1 that is the 50lb monster you refer to. Now that I think of it, the CV- 1982 had the AGC take off....it is a real nice unit... Hammarlund, Central Electronics, B&W and a bunch of others made SSB adapters during the 50's and early 60's. They all had fancy names, but worked pretty much the same. The 455kc IF was converted to 50kc or so, then run through an audio type filter to give it better selectivity. A product detector and audio amp followed. Variations included Q-multipliers, XTAL controlled oscillators, noise limiters, etc. Some history..... When SSB came on the amateur scene in the 50's it was not well understood..... Hams ran their broad IF receivers wide open on AM and relied on a fast acting AGC to keep the diode detectors from overloading. On CW they turned off the AGC, turned down the RF gain, and flipped on the BFO.. for SSB they just flipped on the BFO. This overloaded the Detector, put BFO voltage in the AGC and even if they set the BFO to the correct frequency, made SSB reception almost impossible....also the receivers of the time were not very stable.... Hams could not break their AM habits....Enter the external "signal slicer" to solve the problem...This situation prevailed well into the 60's. What about Collins? Art Collins and his engineers developed SSB gear (with gobs of taxpayer money) for Gen. Curtis Lemay to use on Air Force SAC bombers. When the 75A4 came out in 1955, or so, it cost as much as an automobile.

I'll try to make a copy of the schematic for you.

From: Don Stepka <dts4@...>
Subject: Re: [R-390] R390A SSB Thoughts

A number of people have pointed out in private e-mail related to this thread that a stock R-390 or 390A actually works reasonably well for SSB. For those who haven't benefitted from these comments, I thought I'd post the notion. It is true, at least in my opinion (which is why I haven't built my SSB adapter yet -- I really don't need it badly). For best SSB reception on a stock 390 series radio:

(1) Make sure your BFO is in the center of your IF. (a) Find an AM signal, and carefully center-tune it with the BFO off using the .1 Kc BANDWIDTH position. (b) Turn on the BFO and carefully zero-beat it with the AM carrier using the BFO control (leave the KILOCYCLE CHANGE alone). (c) Pull the BFO knob off the shaft (using a #8 Bristol, #9 Torx, or filed down #10 Torx driver) and carefully replace it pointing directly to zero (straight up). Leave the BFO on for the rest of the procedure.

(2) Turn the RF gain control way down. It doesn't make much difference whether you use the AGC or MGC position of the FUNCTION switch, because the IF level you will use to match the BFO level won't generate much AGC in any case. I usually use fast or medium AGC for a bit of AGC action. Experiment.

(2) Turn the LOCAL GAIN control all the way up. Yes, all the way.

(3) Select the appropriate IF BANDWIDTH (usually 2 or 4 Kc, but maybe 8KC if you find an SSB broadcast station or 1 if the band is really noisy).

(4) Turn up the RF GAIN control until you hear normal band noise.

(5) Tune around until you find an SSB signal. If it is too loud or distorted, turn the RF GAIN control down. The BFO is still at zero, so you want to tune for the most low frequency output (the signal will not be intelligible yet). Now you have the SSB signal in the middle of your IF bandpass. All you need to do is to adjust the BFO (leave the KILOCYCLE CHANGE alone). Depending on whether the signal is LSB or USB, you will need to set the BFO above or below the signal. The BFO is calibrated (approximately) in Kc, so it will end up set to a little less than 1/2 of your selected BANDWIDTH (about + or - 1 for 2 Kc BANDWIDTH, about + or - 2 for 4 Kc BANDWIDTH).

(5 alternate) Set the BFO control up or down according to whether the band you are tuning is LSB or USB. Use about + or - 1 for 2 Kc BANDWIDTH, and about + or - 2 for 4 Kc BANDWIDTH. Now tune around until an SSB signal "drops in."

(6) Make fine adjustments to the BFO and KILOCYCLE CHANGE controls for best fidelity. Once you find where the BFO needs to be for best fidelity, just set it there and tune around, using the KILOCYCLE CHANGE to get the signal very close and the BFO control to "clarify" it (the BFO control moves more easily and smoothly than the KC CHANGE control, so fine tuning is easier).

(7) Adjust the RF GAIN control to control signal level. If the signal is distorted or hard to tune, lower the RF GAIN. If the audio is louder than you want when the detector starts to distort, now you can turn the LOCAL GAIN down a little. You will need to ride the RF GAIN control as the conversation passes from one person to another, and probably tweak the BFO as well. (Freedom from having to adjust the RF gain manually is the primary benefit of a "real" SSB radio or SSB adapter, and as several people have pointed out some of the adapters don't do a very good job. If you want a 390-series radio to do this well, even with an adapter, you really need to modify the internal AGC circuit.) This is all much easier to do than to describe.

From: BOB RAGAIN <RAGAIN@...>
Subject: Re: [R-390] R390A SSB Thoughts

Hello Don and the R-390 group, (and apologies to Boatanchors to whom I sent this the first time): Thanks for that tuning procedure for the R-390 and R-390A. I use mine for SSB reception all the time and it works well enough that I've not considered wanting a SSB adapter.

Here's another shortcut to getting the BFO in approximately the right place for a particular band and bandwidth:

With BFO off, tune across the band and find a nice strong SSB signal with it's Donald Duck jabber. Peak the signal strength by fine tuning the kHz knob. Turn on the BFO and try one side of center of the BFO control, then the other, to find SSB reception. That's the spot to leave the BFO control while tuning the band for weaker signals. Ditto's on using low RF gain. Interesting comment about turning the audio gain all the way up. I'll have to try it tonight. Mine seldom gets turned up more than about 1/3 of the way.

>to try it tonight. Mine seldom gets turned up more than about 1/3 of the way.

It may be that's what's best on your radio. It depends on the particular amount of BFO injection, IF level, and audio gain it has. What you want to do is to keep the RF gain low enough that there's plenty of BFO injection. This keeps the detector distortion down. As long as the detector is not distorting, the RF gain is low enough. By starting with the AF gain all the way up, you know this will be the case. For very weak signals, it will need to be full up to hear them. For stronger signals, the best S/N will be with the IF level (set by the RF GAIN control) a little below the onset of detector distortion and the AF level (set by the LOCAL GAIN control) adjusted for comfortable listening. I have found that leaving the LOCAL GAIN full

up is a fine way to work. The S/N is not always maximized, but it is never objectionable either.

Subject: [R-390] Real simple SSB.. promised follow up

Last month I posted a simple AGC SSB mod (the Dallas Lankford SSB AGC mod (HSN23).. two diodes, no parts removed). I promised those who reponded that I'd post my 'final results' back to the list: (Special thanks to Stefano Kd1cf and to Mark K9TR, for their help on this..)

- -It is so simple and reversible, and makes such a hugh difference in SSB reception, I can't think of a good reason not to do it the next time the IF deck is out! At full RF gain the AGC actually works to provide un-distorted SSB. You can listen to a net without riding the RF gain control. It resulted in no change in AM performance

- -Its just two 1N4148 diodes, one in parallel with R-547 (anode to ..diode 'points away from' pin 2 V-506), one in parallel with R-546 (cathode to.. 'points toward' pin 1 V-509).

- -On real strong, heavily processed signals, there is a slight 'pop' when the AGC first engages. I was able to minimize this two ways:

-I set the limiter control to 2 or 3

-I increased the BFO injection by adding a 33pf 1kV disc cap in parallel with C-535.

The first attempt fooled the AGC with the increased BFO signal. A tip from Mark K9TR, pointed out that I just needed to adjust the neutralizing cap C-525, on the IF deck for a null on the carrier meter. This trimmer is accessible through a hole on the left side panel of the main frame.

From: "Jeff Adams" <jadams@mcqassociates.com>
Subject: [R-390] (Fwd) Re: R390A SSB conversion

I got it from from an article by Dallas Langford (actually there were several iterations of the article) in Hollow State News (HSN). It is REAL simple. 90% of the impact of the change comes from the addition of two diodes to make the AGC attack VERY fast but decay at the normal rate. I HIGHLY recommend the mod. I can't imagine why anyone would do a product detector for the radio with this solution available. This works because the R-390A is designed so that the AGC is based on a signal sample taken before BFO injection, so the BFO does not fool the AGC!

The AGC mod is:

--one 1N4148 in parallel with R 547, 'pointing' away from pin 2 of V506A.

--one 1N4148 in parallel with R 546, 'pointing' toward pin 1 of V509A.

--(I soldered both directly to the resistors)

For the last 10% of the improvement, the system could stand a lot more BFO injection. I am not sure this is worth the extra effort. 2 of my 3 radios have it, and there is more variability between the radios than impact from this change, based on how the radios play. But as long as you have the deck out...

The BFO mod:

--add a 47 pF cap in parallel with C 535

--redo the BFO neutralization (this is the trimmer cap on the IF deck that is accessible through a hole in the left side of the main frame near the front panel. Simply adjust it for minimum carrier level meter reading with the BFO on.)

Finally, there are some things you can do to fool with the AGC time constant, but I can not see why anyone would want to do that.. Let me know if you'd like to know more about those changes.

From: SBJohnston@aol.com
Subject: Re: [R-390] Re: R390A SSB conversion

For me, it reduced the distortion on the leading-edge of SSB signals, and allowed operation with relatively normal RF gain settings on even strong SSB signals. I found no penalty on reception of other modes.

Last week, while working on the 4 kHz filter problem mentioned earlier, I had the opportunity to try my SSB-modified Motorola at home against the unmodified EAC we use at work, and the difference on SSB was night-and-day. I had difficulty adjusting the EAC to handle the varying signals present on a SSB military net I was monitoring, but the modified Motorola had no trouble. AM performance, using both the built-in envelope detector and my external sync detector, were identical as far as my ears could tell. CW was somewhat better on the modified unit.

Subject: [R-390] Re: R390A SSB conversion

Fraser wrote a good question back to the list:
<<The mod seems relatively easy, but what exactly does it do to SSB reception?
>>

The question is about the two diode SSB mod that I described that Jeffrey L. Adams copied back to the list. I wish I was bright enough to have figured this out myself, but the credit goes to Dallas Langford, and about 10 years ago. What does it do? From the operator's perspective, it allows you to copy SSB with the RF gain all the way up. Without the mod, you have probably noticed that you can reduce the RF gain control and copy signals pretty nicely. If you are trying to listen to a net or both sides of a QSO, one hand has to be on the RF gain.. With the mod, just turn up the gain and let the AGC do it's thing! Signals sound as good as on my KWM-2 (which for Collins fans is new enough to have SB 8A from the factory).

I am not an Electrical Engineer, so this is probably an oversimplification, but

electrically it just allows the AGC to attack fast enough to reduce the gain to a level where the BFO can mix effectively in a diode detector. It works on the R-390 and R-390A because these radios sample the signal for the AGC ahead of BFO injection. The BFO injection level is not a factor in gain control.

On most Ham rigs without product detectors of this vintage, the BFO is injected where the AGC gets its signal sample. The AGC gets fooled by the signal level presented by the BFO so it is reacting to the BFO not the signal. So this kind of mod would not work for them. Product detectors seem to be very tolerant of widely varying differences in signal and BFO levels, so with them its not an issue.

I hope I have not confused this issue too much. The mod is so cheap, simple and reversible, why not just try it?.. like the late night dicer/slicers.. 'it really really works' (really).

Subject: [R-390] SSB adapter for R-390A

I got quite a bit of interest from the list on this topic, so I'll arrange to post the information. Josh Rovero has kindly offered to post it on his web page, so I'll work with him to get the information out. I'll get a schematic scanned and provide it to Josh. A little more detail to whet the interest of those who asked for more information. The circuits are pretty simple, but the nice part is the ability to use the receiver as if it was all built in. The IF output from the R-390 is fed in parallel to a MC1496 product detector, and to a two transistor AGC amplifier and voltage doubler. The output of the product detector is amplified in one transistor and then fed to the R-390 audio at the diode load. A mode switch allows the adapter to be bypassed and the receiver works on AM and CW just as before. The AGC was to be switched also, but I found it works OK in parallel with the R-390 AGC (tha adapter provides the fast attack needed for good SSB reception). So the carrier meter and AGC time constant switch on the radio still work. I had to add a separate BFO oscillator in order to avoid any wiring to the receiver that didn't go to the terminal strip. This doesn't seem to affect the stability significantly. The BFO can be tuned to offset for sideband selection. Pretty simple- the only thing it doesn't do is to select sidebands without retuning the receiver. The audio is smooth and clear. It seems strange to tune across the amateur bands and have the radio sound like my R-4C. Some have asked if kits are planned- I don't have a PC board layout, but if someone wants to undertake that part of the kit I may be able to put together the rest.

Subject: [R-390] SSB Adaptors

A few weeks back someone mentioned using an HP312B as a SSB adapter with an R-390A. I thought this was an interesting idea and was able to acquire an HP312C at a reasonable price. It may not have tubes (do nixie tubes count?) but it should have honorary status for its weight and size. It's bigger than a 390A and almost as heavy.

Anyway, I've been using it with my R-392 and it is excellent. I ran the IF output of the radio to the 312C input and its audio output to a bench amp. Adjust the 312C freq to 455 kHz and away we go. The vernier frequency control on the 312 provides excellent SSB and because the unit tunes over the full BW of the radio's IF, you can actually tune in a number of adjacent stations without retuning the radio. The 312C has a big back-lit meter that is great for relative signal strength. Also, it should work with virtually any receiver regardless of IF frequency, as the 312C covers from essentially DC to 18MHz. All in all a pretty good solution - except for the size of the thing - or at least until you can find a nice CV-591 or equivalent. Thanks to whoever suggested this approach.

Subject: [R-390] SSB Adapter

Regarding the R-390A SSB adapters I don't believe I have seen anyone mention the SSB mod by Dallas Langford, published in HSN about 1991 or so. It involved increasing the BFO injection and improving the AGC attack time, along with better AGC release times.

I have done many of these such mods and it is my favorite, although not an actual product detector it is hard to tell otherwise. The mod is done only on the IF deck, and does not affect AM reception. This is a pretty easy mod to do and easy to take back out if you want to later- only involves a few components such as a diode, resistors and a few caps- no drilling or extra tubes, etc. WA5THJ.

Subject: [R-390] Langford 2 diode SSB mod.. An update

I've noticed some renewed interest on the list lately in this real simple SSB mod (two diodes) to the IF deck (this is NOT the "black box" that makes AGC from the line audio). Initially, I'd thought that there was one compromise. The only real problem I'd had with the mod was a "popping" on attack on real strong signals. I was able to minimize it with the limiter. I'd traded notes with some other list members who had had similar experiences.

BIG DISCOVERY (for me) a few months ago. SSB should be copied using slow AGC (finally read my TS-850 manual. Real men don't...). At that setting the popping is gone. The radios had been as good as my 1964 KWM-2 before SB-8 (the AGC update) now they are as good as the KWM-2 after SB-8. Anyone using this mod at Medium or Fast settings should try this. For those who have never heard a radio with this mod, you should try it before investing in an SSB adaptor. It is VERY reversible, if you decide you do not like it. Contact me for a description if you do not have it.

Subject: [R-390] Lankford 2 diode SSB mod

What a flurry of requests for details of the mod. I hope everyone will be OK with my just answering via the list. First, apologies to Dallas Lankford for misspelling his name. Credit for these mods goes to Dallas and H. Cornelius. A similar mod for an R-390 (non-A) is described in QST. Hollow State News Issues 1, 10, 23, 27 and 36 cover various versions of the mod. My notes are based on the version in HSN 23: The AGC mod is:

- one diode in parallel with R 547, cathode as follows
-----|<-----pin 2 V506A

- one diode in parallel with R 546, cathode as follows
----->|-----pin 1 V509A

I used good quality 1N4148's piggy backed to each resistor. Dallas suggested a 1N270 (ECG 109) in HSN 23, and either 1N4148 or 1N914 in HSN 27. He is pretty specific that the diode must have very high back resistance so germanium diodes are out.

This is the simple change. If you want to go a little more sophisticated, get copies of HSN 10, 23 and 27 (the article in 1 is essentially repeated in the others). Back issues are available from Ralph Sanserino (sanser@GTE.net). I cannot, in clear conscience reprint these for you and 'end run' Ralph.

You can also add more BFO injection by adding a 47 pF cap in parallel with C -535. The R-390A derives its AGC signal ahead of the point where BFO signal is injected, so the radio does not get fooled by the BFO signal. I got mixed results with this. It does require readjusting the trimmer nearest the front panel on the IF deck that is accessible through the left side panel of the main frame. The manual tells you how to do it. Have fun.. this mod makes a huge difference..

Getting ready to do the Lankford 2-diode SSB mod on one of my 390A's. I have on hand both 1N4148 silicon and 1N270 (actually NTE-109 equivalent) germanium switching diodes. Will my ears be able to tell which type was used after I'm done, or is the requirement for switching action at these frequencies so relatively slow it would make no difference?

Date: Fri, 29 Oct 1999 09:22:52 -0500
From: "Dr. Gerald N. Johnson, P.E." <geraldj@ames.net>
Subject: [R-390] Re: Silicon vs. Germanium for SSB mod

You have plenty of voltage, the main difference at audio will be the forward drop, the germanium being lower than the silicon. Since you adjust the AGC action by the line level control you can easily compensate for the voltage drop difference. The silicon will last longer if there's a lot of voltage, less leakage and higher voltage rating.

73, Jerry, K0CQ

From: DCrespy@aol.com
Subject: [R-390] Silicon vs. Germanium for SSB mod

While I cannot vouch for it, Lankford says that it does make a difference. Definitely silicon. I have modified three IF decks with excellent success with 1N4148's or NTE equivalents (the NTE's have a slightly higher voltage rating, I like that for BA's).

Please note that this is NOT the mod that makes AGC voltage from the "line output". AGC level is NOT adjustable with the line level control. If you follow the schematic, this mod makes the AGC "fast attack". The diodes permit the time constant cap to charge without the time constant resistors in place, but it must discharge through the resistors. Hence fast attack/slow decay..

From: "Dr. Gerald N. Johnson, P.E." <geraldj@ames.net>
Subject: Re: [R-390] Silicon vs. Germanium for SSB mod

Yes that **internal mod needs silicon** otherwise the germanium will leak too much

and modify the circuit too much.

Date: Sat, 30 Oct 1999 09:00:58 EDT
From: DCrespy@aol.com
Subject: Re: [R-390] Silicon vs. Germanium for SSB mod

I am a mechanical, not electrical engineer, but I'll try to explain it as best I can. If you have TM 11-5820-358-35, read about the AGC circuit on pages 33 and 34.

The reason SSB sounds distorted with conventional AGC is that there is no carrier to track, so the AGC might have to 'reset' each time a new word is spoken. So the first syllable of a word does not get the benefit of gain control.

The time constant circuits (R546/C547 and R547/C548/C551) must charge their capacitor(s) completely before full AGC voltage is developed. The charging rate is limited by the current that can flow through the resistor. The diodes effectively eliminate the resistor on the charge cycle, and get the AGC voltage up to full level as fast as possible. This REALLY helps track that first syllable! High back resistance diodes keep the discharge cycle function as intended in the original design.

Lankford points out that the AGC rates after the mod are still not optimal, and in the HSN article talks also about improving the rates after the diodes are put in, by manipulating the capacitor values. Lankford also noticed (as I did) that the AGC is now more "aggressive". That is, in addition to faster attack, the absolute voltages are higher. So stronger signals will get more gain reduction than before the mod. This may also be one of the reasons the mod works. Now the level of BFO injection is higher relative to the signal at the detector.

I hope this helps. Maybe this will stimulate some feedback from some of the EE's out there, who understand this better than I do.

Subject: Re: [R-390] SSB adapter for R-390A

Glad to hear that you're having fun, Jan. To answer the questions, C32 is just a bypass cap 0.1 mf. The AGC FET is a 2N3819 from Radio Shack. I trimmed many of the bias networks to get the best waveform or dynamic range, so different transistors may need different components. I made a tuning cap by twisting all but one plate off of a small variable cap. You don't need much variation to move the BFO a couple of Kc. Do try the AGC, it's got the fast attack, slow decay characteristic needed. As we've heard on the list, having a good AGC is more than half the battle. I was planning on using a LM565 for the phase lock loop, feeding the LM1496. Haven't had time yet to start on breadboarding that part of it. I believe that the feedthrough of the R-390A BFO may be enough to use the synchronous detector for SSB as well as AM. This would eliminate the separate

BFO, and make the adapter less complicated.

Subject: [R-390] Lankford AGC mods, ST. Julians finally finished

Having finally buttoned up a St Julians creek disaster after almost a year of piddling away and some help from this group, I would like to say the hours weren't worth it but the "experience" was everything! I really learned a lot.

To begin, as a matter of principle, I am not one who favors mods unless they get me to the end of being able to use something better. Specifically, I like listening to some of the military freq's such as 11.175 usb. Admittedly, I also have a couple of R1051B's that will do the job quite nicely. However, given that this unit was sort of an experiment to see if I could ever get it running, I felt it might be worth the time to do a little experimenting. So I first disassembled the unit down to the module level and removed the rf deck, took all the cans and racks out, removed the front panel to refinish, and started by getting the modules except the rf deck working in another 390A chassis. As far as cleaning, an aerosol degreaser was used just prior to a hot water washer to clean up everything, especially the rf deck. I covered the cans that couldn't be removed with duct tape. Then I final rinsed with a gallon of distilled water and then put them in the attic during the summer for a week to dry out. So, finally this fall, it was time to start the reassembly.

Mostly, I wanted to make sure everything was working before I started "jacking" with it. My first attempt was to do the IF mods on the unit per the suggestions of the Electric radio series in #26 using 6jh6's and adding a diode and removing a couple of resistors. My ear told me that this wasn't really satisfactory. (Fortunately, I had not cut the swamping resistors in T501,2,3) So basically, I removed/reversed that suggestion to the Lankford way. This is really simple, remove one resistor add two capacitors and add two 1N4148 diodes. Dr Langford suggested changing C551 to 1.22uf for the slow AGC and adding a .47uf to lug 9 of S107 after lifting the white wire to ground for the medium agc. I did this and found that I only used the medium position so I undid the 1.22 part and only left the .47uf attached to lug 9 of the s107. I just used a dab of clear silicone rubber to glue the cap to the inside of the front panel and the next day it was firmly attached and yet still removeable. Bottom line: I can barely tell the difference between the 1051B and the 390A. However, I did try the trick of changing R541 from 270 ohms to 1000 suggested in the Electric radio series. I felt that I just didn't have quite enough AGC and changing this resistor made a big difference. My feeling was that because I have that "repaired" Z503 using a fixed inductor and cap that maybe it isn't quite at resonance but this seemed to get around the problem. I would sure hate to change Z503, boy would that be a job even if one could find it! The last couple of things involved adding a 47pf cap in parallel with the BFO injection cap per the Lankford way. And..... that ballast tube bothered me. I just hate to spend \$17 when there is less expensive ways that aren't degrading. The first thought was to go 12BA6's and jumper the ballast socket. I really didn't like the look of that hollow

spot. So, for another twist on the ballast tube alternative, I used a "pulled" 15DQ8 TV type tube and moved the wires to # 3 and 4. This is so minor and given that I had to remove the BFO shaft to change the injection cap anyway, it seemed a simple and cheap way to go. I tried to use some 12v tubes but found that the low side voltage was a tad high. The 15DQ8 put almost exactly 12.6 volts on the low side headed to the PTO and BFO tubes. I know this sounds significant, but when all was said and done, I had an IF deck that really handled the SSB and still made the BBC sound nice.

Then, I tried the RF deck mods suggested in the ER article. For whatever reason, the bottom line here was that after I had good AGC with almost no distortion, modifying the rf deck to 6HA5's for mixers and changing the RF amp, created unacceptable problems. First, I lost a significant amount of AGC. Secondly, I couldn't open the rf gain completely without putting it into oscillation or having almost no rf gain control with another type tube. So, I reversed the entire rf deck mods and took it back to original. Perhaps there is something else wrong in the rf deck or I missed the obvious when changing the wiring for these mods but after reversal, it again ran beautifully.

In summary, I would highly recommend the IF deck mods suggested by Dallas Lankford. They are simple and easily reversible. There are no holes or drills and they allow a fantastic engineering marvel to copy SSB which was just coming on line during early life and development. Primarily used for copying the fleet/unit broadcast in it's 8 and 16 mhz bandwidth, R390A didn't see a lot of SSB until the end of it's life when the 1051 series came to replace it in the Navy at least.

The final touch was putting on Tom Marcotte's replacement tag. When the choice is no tag or a \$9 almost authentic one, it isn't really a hard decision. I really take my hat off to Tom for taking the time to develop them and to Dan Arney for the covers. Those two guys deserve a lot of credit for the labor of love to make available the replacement parts. Sorry this ran so long.

Subject: Re: [R-390] SSB adaptors

There seem to be several options for SSB: - -modify the AGC circuit in the IF module to speed up the attack time. My R-390A isn't bad once the AGC is improved, even without a product detector. However, it involves modifying the radio.

- -buy a contemporary tube SSB adapter CV591, HC10, GSB1, etc. This tends to be expensive these days.

- -I built a solid-state adapter which provides outboard product detection and fast attack AGC. I'm real happy with this, because it feeds the audio back through the radio. However, this has to be a construction project. I now have an descriptive

file which I can e-mail to anyone interested.

- I saw an ad on the net for an offboard product detector similar to mine, about \$130. No AGC though, so it would require the mod above to provide what I consider satisfactory performance. If anyone is interested, I'll try and track down the web site.

Subject: Re: [R-390] SSB adaptors

Another possibility, I've been thinking of trying, is feeding the IF into an old HP wave analyzer like the **HP 3590**. These are variable bandwidth frequency selective voltmeters with a product detector and usb/lsw selection. Input impedance is about 100 kohms and the bandwidth opens up to 3 kc.

I got lucky and found a pair surplus for \$25 each. They are large, about the size of the R390 but should be pretty cheap because of their age and lack of market for them. The plug ins have a built in tracking generator too, so you can hook a counter on it to see what frequency its set to, if you dont believe the mechanical or nixie display.

Subject: RE: [R-390] SSB adaptors

Abt 3 months ago I informed this ng list abt product detector DIY project. I received abt 70 requests for the schematics. The project is an external adapter comprising:

- -AM-sync detetector,
- -product detector using tunable BFO for SSB/CW
- - IC audio amp

Its quite simple design using easy to find parts. It plugs to ext IF of r-390x. No mods needed for yor r-390x. I have used it now 2 months and can't live without it. Although it has no AGC, it performs quite well having r-390x set to internal AGC (not MGC). I can send via e-mail the schematics (2 gif files) by request. Yrjo OH2BRY, Helsinki, Finland

Subject: [R-390] R-390A SSB Adapters really needed?

Are SSB adapters really needed for the R-390A?

I use my Motorola R-390A to receive SSB all the time, and have never found it difficult, once I got the BFO knob set correctly: when pointed at the 0 mark, it really needs to be 455 kHz. This is very easy to set - hook up the frequency counter to the plate of the BFO tube thru a DC blocking capacitor, set to 455.000 kc (with as much precision as you want), and replace the knob pointing at zero. After doing this, tuning SSB on this R-390A works this easy: set BFO to 0, tune signal for zero beat. Turn BFO knob to +/- 2 or 3, until signal is readable. Adjust RF Gain as needed. Works good for me... Am I missing something these converters have to offer?

Subject: Re: [R-390] R-390A SSB Adapters really needed?

Hello. In the strictest sense a SSB adapter is not needed for the R-390A. However, because this radio is arguably the finest receiver ever made, many on this list are perfectionists and demand performance consistent with the other functions of the R-390A. The government and Collins recognized this and a sideband adapter was eventually built for use with this radio. The real problem is on strong signals there is a lot of distortion on SSB. Of course you could adjust the rf gain to compensate, but ideally it's nice to just sit back and listen without having to play with the gain. I hope this answers your question.

Date: Mon, 14 Feb 2000 19:08:51 EST
From: DCrespy@aol.com
Subject: Subject: [R-390] R-390A SSB Adapters really needed?

What is missing on the base radio is a way to keep the BFO at a high enough level to decode (insert an adequate carrier RELATIVE to the signal) SSB. Since the R-390A inserts the BFO signal after the AGC amp gets its signal, the BFO is already at a pretty high level. So the problem becomes getting the AGC to react quickly on SSB peaks to keep the signal level down. This is why the fast attack/slow decay AGC mod works.

You have probably noticed that you have to reduce the RF gain to copy SSB.

When trying to follow a net, I had to ride the RF gain control. The AGC change eliminates that, you can turn the gain full up and the AGC does the work.

Of course a product detector is a more complete solution, but an AGC change gets you 90% there with just 2 diodes!

From: "B.L.Williams" <B.L.WILLIAMS@prodigy.net>
Subject: Re: [R-390] R-390A SSB Adapters really needed?

The only reason I mention this is that some people make a mistake on tuning the BFO. And, this is something you can test yourself for best reception using SSB on the R-390A . I made the same mistake too before stumbling across the correct procedure per the -10 after a long time of incorrectly tuning SSB stations. I felt pretty dumb about it until I found out that others haven't really looked at the tuning procedure in the -10 either. I mean, it is big letters and the photos look like it is made for someone who has never seen a radio, right? So, I skipped over all that in the beginning.

You offset the BFO depending on your filter setting. If you use the 4 kHz filter then you offset either USB or LSB by 2 on the BFO. The general rule is to half the bandwidth of the filter on the BFO offset. I rarely use anything but the 4 kHz filter.

You can play around with this on your radio and I bet you will find the best SSB reception is using the -10 method. Try it zero beating like you said on a medium strength station. Then, offset half the filter setting. Then maybe offset more and try to retune the best you can. You can hear the difference. Mine is a Motorola too. Anyway, the clearest and most accurate reception is to use that way to tune.

Subject: [R-390] SSB and the R390

I look at it this way I have three good transceivers that do SSB very well. Keep in mind I am looking at SSB reception from the point of view of a Ham Radio operator. The R388, R390A that I have do a fine job on AM and a single transmitter on SSB, such as utility stations. In a round table situation where you are talking to several other people it gets very interesting because of the differences in signal strength I am riding herd on the RF gain to control distortion. As you all know my R388 and R390A sit beside my bed all the controls are in easy reach so in a semi-dream like state Listen to these radios in the dark of night. I started with swl radios beside my bed when I was ten years old in Thermoplis, Wyoming back in 1961. I can't remember what I had, it was either an RCA, or a Zenith. I can remember listening to this radio hidden under a blanket in My basement bed room of my house. I was unable to go out to play in the falling snow because it was contaminated by fallout from the latest hydrogen bomb test from the Soviet Union. Of course I was listening to Radio Moscow while this was

happening, it was deliciously exciting.

From: DCrespy@aol.com
Subject: [R-390] R-390A SSB Adapters really needed?

Credit for these mods goes to Dallas Lankford and H. Cornelius. A similar mod for an R-390 (non-A) is described in QST. Hollow State News Issues 1, 10, 23, 27 and 36 cover various versions of the mod. My notes are based on the version in HSN 23:

The AGC mod is:

- -one diode in parallel with R 547, cathode as follows
-----|<-----pin 2 V506A
- -one diode in parallel with R 546, cathode as follows
----->|-----pin 1 V509A

I used good quality 1N4148's piggy backed to each resistor.

This is the simple change. If you want to go a little more sophisticated, get copies of HSN 10, 23 and 27 (the article in 1 is essentially repeated in the others). Back issues are available from Ralph Sanserino (sanser@GTE.net).

You can also add more BFO injection by adding a 47 pF cap in parallel with C-535. The R-390A derives its AGC signal ahead of the point where BFO signal is injected, so the radio does not get fooled by the BFO signal. I got mixed results with this. It does require readjusting the trimmer nearest the front panel on the IF deck that is accessible through the left side panel of the main frame. The manual tells you how to do it. Have fun.. this mod makes a huge difference.. Harry KG5LO Saline MI

Subject: Re: [R-390] Panoramic Adapter

>Are there any recommended panoramic adapters for the R-390a?

The Communications Electronics Inc (now Watkins-Johnson) SM-8512 and SM-8513 were designed and sold as panoramic adapters for the R-390(a). They came with a kit and instructions for proper interconnection to show 50 kHz bandwidth. They are 2 rack units high and look great with the R-390. The SM-8510 and SM-8511 were designed for the R-388 and are very similar. They can be easily retuned to use with the R-390. Many later model WJ SDUs also do a great job with the R-390.

> By the way, I peaked the RF deck using the 100 kc calibrator as a signal
> source as I didn't have a signal generator handy at the time. Seemed to
> work ok, but is there a downside? I have a URM-25 that will be gone
> through shortly, so I will be able to do the job properly.

I have had good luck with the calibrator for peaking up the rf deck, including the trackin IF's. The cans on the tracking IF's are marked with there operating frequency, not the frequency the radio is tuned to, so for example, the 0 to 8 mcs band is labeled something like 17 to 27 mcs. Clearly, peak these while tuned to about .9 and 7.9 mcs. May be obvious, but slugs are peaked when "fully in" to the coil and caps are peaked with slugs "fully out".

On the BFO injection, I would also look at the BFO tube. I had one go 'soft' about two weeks ago on a radio with the two diode mod, and it worked as you described.

A new tube brought it back to life! On the mods, following is from my notes, taken from the original articles in Hollow State News. At one time (an HSN article) the 1N270 was recommended for this application. Some list members have suggested that it's back resistance is not high enough for the application. My experience using it for a similar 51J mod bear this out. If you used 1N270's, I'd switch to 1N4148's. Notes follow:

Credit for these AGC mods for improved SSB goes to Dallas Lankford and H. Cornelius (Hollow State News #1,10,23,27,36).

My notes are based on the version in HSN 23:

- -one diode in parallel with R 547, cathode as follows -----|<-----pin 2 V506A
- -one diode in parallel with R 546, cathode as follows ----->|-----pin 1 V509A

I used good quality 1N4148's piggy backed to each resistor. This is the simple change and it makes a HUGE difference.. If you want to go a little more sophisticated, get the HSN copies via Ralph Sanserino (sanser@GTE.net)

You can also add more BFO injection by adding a 47 pF cap in parallel with C 535. With the R-390A's circuit layout this does not fool the AGC. I got mixed results with this. It requires readjusting the lone trimmer on the left side of the IF deck (see the manual).

Subject: [R-390] PD-1 SSB Adapter for R-390A

Have been using a unique product for several days now, a solid state SSB Adapter. Electric Radio Magazine has these for sale.....\$129.95 + \$4.50 shipping. Comes with wall wart power supply, connector and cable for connecting to the IF Output. Since the audio is line level output, you will need a amplifier and speaker. I am using an older 70's tuner/amplifier and a Radio Shack Optimus Pro X-7 speaker. I have never heard such audio recovery from the 2 kc filter. If you think that a 2.1 or 2.4 filter provides great ssb reception, you aint heard nothing yet. The 2 kc mechanical is super. The selector switch has off, am, lsb and usb positions. There are three potentiometers inside for tweaking to your particular amplifier/ setup. I can honestly say, that this is the best ssb I have ever heard from a

R-390A. Also works great on my SP-600. Different models are available for the 51J/R-388 series of receivers also.

Subject: [R-390] Lankford AGC mods...need more info.

I have tried to install the "two diode" Lankford mod. There are at least two versions of the mod I have found:

1.-- I have gotten information from the list that "Dr. Lankford suggested changing C551 to 1.22uf for the slow AGC and adding a .47uf to lug 9 of S107 after lifting the white wire to ground for the medium AGC."

2.--I have also gotten information from the list that "the AGC mod is:

- -one IN4148 in parallel with R 547, 'pointing' away from pin 2 of V506A.
- -one IN4148 in parallel with R 546, 'pointing' toward pin 1 of V509A.
- -disconnect the wire at pin 1 of V 506A (goes to the AGC switch) and ground
- - it, then add a 2uf cap at the AGC switch between pin 8 and ground.
- -add a 1.2 uf (I guess 1 uf would work) cap at the AGC switch, between pin 9 and ground."

It is obvious that these are different versions of the same mod. I am particularly interested in the statement, "disconnect the wire at pin 1 of V 506A and ground it." Which is "it"? From my and Don Frazier's evaluation of the schematic, if I ground the wire, I kill the AGC switch function. If I ground the plate at pin 9, I kill the tube and the carrier level meter. The first version of the mod sounds more like the one I should try. So, what is the AGC mod? Which version is the correct one? I don't think anyone would complain if someone faxed me a copy of the article. Can someone send me a fax of the mod or describe it in sufficient detail for me to accurately implement it?

From: DCrespy@aol.com
Subject: Re: [R-390] Lankford AGC mods...need more info

Some insights: There were several versions of the mod. They were explored in MANY issues of Hollow State News. For the AGC: the BASIC MOD IS ONLY THE TWO DIODES in your paragraph 2 below. All of the articles reference this. It was

the subject of a QST article in the late 80's (for the non-A R-390). This is 95% of the effect. The rest of Lankford and Cornelius experiments were about playing with the AGC time constant. The rest of the "noise" is about this, except: for BFO injection: it was just adding a 47 pf cap in parallel with the BFO coupling cap, to increase injection. I would not do anything else until you have put in and tried the diodes ! Good Luck and 73 Harry KG5LO Saline MI

Subject: Re: [R-390] Lankford AGC mods...need more info.

All of the info was first published in Hollow State News (HSN) and is still available. Ralph Sanserino (sanser@GTE.net) handles back issues (\$1 each) and subscriptions. I bought the whole set, and am a current subscriber. It has been worth every penny. I highly recommend it, but I cannot copy it wholesale in clear conscience and end run Ralph. For just the SSB AGC mods you'll need numbers

1, 10, 23, 27 and 36. Seems like the R-390A FAQ site has the complete index. Contact Ralph! The mods each were a development of the previous. It started with Cornelius and was updated several times by Lankford. While they each look a little different, they are actually evolutionary, so if you plan to go 'full boat', just get the last couple of issues. The work is thorough, with complete explanations of why, with experimental results. The text is pages long for most of the articles, so you will get a good feel for where the author started and why he did what he did!

This Journal started years ago as a R-390A users group (before the days of internet mailing lists) and is still rolling. It now covers also the 51J series radios and the SP600s! there are also a few articles on HQ-180s and other high line / high performance commercial grade tube radios... Great newsletter!

Subject: [R-390] Lankford "SSB" mod

Just for fun this weekend decided to try the Dallas Lankford "SSB" 2-diode mod -- it's cheap and easily reversable. Initial impression: It's not perfect, but it's almost getting something for nothing. Did not notice any deterioration of the AM signal and did not have to ride the RF Gain nearly so much with the BFO on. Only on the strongest of SSB signals was the RF gain reduced back a bit (not nearly as much before the mod) and the weak SSB signals were still audible.

Used the balanced input with the UG-970 (thanks Glen!)

Will do more listening just to make sure of my findings. Have not tried increasing the BFO injection.

From: "Walter Wilson" <wewilson@knology.net>
Subject: Re: [R-390] Lankford "SSB" mod

I tried the Lankford 2-diode SSB mod, and later added the extra capacitor to increase the BFO injection. I seem to recall that increasing the BFO injection significantly reduced the distortion on the stronger signals. Now I can run the RF gain all the way up on SSB signals and let the AGC action do the rest. Works for all but the very strongest of local signals. I've done this mod on two R-390As, and the third one that's on the bench will get it next. I have not yet done the "complete" Lankford mod that changes the AGC capacitors to change the attack/release time constants. Someone who's modified the AGC capacitor values might comment on how much advantage the faster attack time constants seem to add.

From: pbigelow@us.ibm.com
Subject: [R-390] Lankford SSB, part II

Tried the "Lankford SSB" mod -- results great! Tried increasing the BFO injection with the 47pf cap paralleled with the C535 -- results greater still! Now only the STRONGEST stations have a little distortion (still listenable though), and, if annoying, just back off the RF Gain just a *little* bit. Otherwise, it's almost like having SSB! This is one whale of a modification. What a deal. \$2.00 worth of parts, nothing cut or removed, and IT WORKS.

Listening quality is enhanced by setting the AGC to "SLOW".

Subject: [R-390] 1N270 vs 1N4148 for "Lankford SSB"

Hello, Any opinions concerning the 1n270 vs the 1n4148 for the Lankford SSB mod? Any reports from the people that inquired about the mod over the past week?

Date: Tue, 15 Aug 2000 09:44:00 -0400
From: pbigelow@us.ibm.com
Subject: [R-390] "Lankford SSB" part 3

First step: 1N270 - works well, some distortion on STRONG stations
Second step: added 47pf - worked further in reducing STRONG station distortion
Third step: 1N4148 - replaced 1N270, virtually eliminated STRONG station distortion

Also, using the 1N4148 seemed to eliminate a momentary "pop" sound heard with STRONG stations when in the FAST AGC position. Still evaluating. So, the arrangement of the 1N4148 and the 47pf cap seems to be best, so far. Any expermenters out there with results from using other diodes? 1n4448, perhaps? At this point, I see almost no need for an external SSB adapter -- unless slight fiddling with the BFO knob is just too much to bear.

STRONG stations are virually distortion free and the weak signals are quite intelligible. In no case is the RF GAIN control touched. If the sound seems a bit thin, switch to the 4kc position. Wow! Bandscanning in SSB with an R-390a. Who'd have thought? AM and CW stations seem to be unaffected.

Almost makes you wish there was an USB/LSB engraving at the -1.5 and +1.5 positions on the panel. Has anybody compared the "Lankford SSB" against a CV-591?

Any point to having a CV-591 anymore?

From: "Dr. Gerald N. Johnson, electrical engineer" <geraldj@ames.net>
Subject: Re: [R-390] "Lankford SSB" part 3

The 1N270 is a fine diode but in the AGC circuit its back leakage is probable excessive and limits the development of that AGC voltage, and causes the AGC voltage to leak down.

Once get to the 1N4148 family, the 1N914 or 1N4448 should act IDENTICALLY for this application. Their main differences are in how the package is assembled to the same diode chip. Its a silicon junction diode, the 1N4148 holds it between a couple metal slugs surrounded by glass. The 1N4448 does it the same way in a smaller package, the 1N914 has a cats whisker to make contact on the metalized side of the chip. At least it used to. I suspect today that diodes are made with all three numbers on the same production line from the same parts since all three have the same specifications for speed and reverse voltage. The slugs allow greater current than the cats whisker.

From: pbigelow@us.ibm.com
Subject: Re: [R-390] "Lankford SSB" part 3

Functionally there may be no difference but these are my reasons:

1. Preserve the original part.
2. Make it VERY easy to restore back to original should I ever care to
3. Preserve whatever temperature compensation is in the original part

When I went into this project, I was very skeptical and wanted to be sure that the entire mod could be removed if it proved unsatisfactory. Thus, no parts were cut or removed.

Subject: Re: [R-390] "Lankford SSB" part 3

Diodes including 1N914 USED to be painted with black or dark blue paint to prevent them being photosensitive. Actually ALL semiconductor junctions (including the old selenium rectifiers) are photo sensitive and applied light will modify their measurements and performance. Somewhere deep in the test specifications for all except those rated for photon reception is the requirement that they be tested in total darkness. Some of the early video chips were nothing more than dynamic ram with a quartz lid instead of solid epoxy in the case... then they used an analog output instead of the digital comparator output to get gray scale.

A layer of scotch #33 or 88 around a glass diode should keep out most of the light.

Subject: Re: [R-390] "Lankford SSB" part 3

All 1N4148's that I have seen are in a glass case. I just visited the Fairchild web site to verify this. The case style for a 1N4148 is DO-35. This is listed as glass. I thought that there were differences in turn on speed in the 1N914 and 1N4148 as well as PIV differences, but have not been able to confirm that.

> 1N914's are made of glass. When you subject 1N914's to room light the photo-electric currents creep up and sometimes "funny" things can result. Try it if you dont believe me w/ a meter.

I would expect that the real 1N4148's would also exhibit photoelectric effects. I say real because there may be some company out there that places a 1N4148 die into a plastic case. Much like the 2N2222 vs the MPS2222 and PN2222 transistors.

Subject: Re: [R-390] 1n270 vs 1n4148 for "Lankford SSB"

I have used the 1N4148 in 3 decks that I have modified. All worked GREAT, confirming your terrific results! While I have never tried the 1N270 in an R-390A, I have in my 51J-4. It was a similar Fast-attack-slow-decay AGC mod (Orr's from Ham Radio magazine, with a product detector). The AGC action was terrible until I replaced the diode with a 1N4148 (confirming your experience). As Jerry Johnson observed, the 'back resistance' for this diode is apparently not high enough for an AGC application like this. Lankford noted this in later editions of HSN, and recommended the 1N4148 over the 1N270.

> Any reports from the people that inquired about the mod
> over the past week?

I have responded in the last week to another (?) Paul with notes about the Lankford mod, but have heard nothing yet about his results.

From: DCrespy@aol.com
Subject: Re: [R-390] 1N270 vs 1N4148 for "Lankford SSB"

I think it works so well, because the AGC is based on a signal collected before (ahead of) the BFO injection point. This means that the BFO injection levels can be quite high, giving plenty of "carrier insertion". Most designs pick up a signal for AGC at the same stage (at the diode detector) where the BFO signal is injected. This means that if the injection level is too high, the AGC will follow the BFO, not the signal. So designers had to reduce the BFO injection level to an absolute minimum. Product detectors work with AGC because they have little or no BFO signal present at the input to the detector (where signals would be sampled for AGC). Audio derived AGC would of course work with either.

Subject: Re: [R-390] More SSB problems with R390A

The standard AGC doesn't have the holding time constant long enough for SSB, nor the attack fast enough and distortion on SSB with the RF gain full up is normal. No receiver made before SSB became the standard works much better. You can do one of several things: Add a product detector, increase the coupling capacitor between the BFO and the diode detector, change the AGC constants, install the AGC diode mod, or run the RF gain backed off for SSB.

From: SBJohnston@aol.com

Subject: Re: [R-390] More SSB problems with R390A

>If I back off the RF gain, the signal becomes clear.

That is normal, in my experience. It is a matter of proper signal-to-BFO-level ratio. If you are trying to demodulate an SSB signal using a diode (envelope) detector, you must provide a local "carrier" signal (BFO) and it must be in at least roughly the right proportion to the level of the sideband. Think of it this way... if you have the RF gain turned up, the sidebands look real strong compared to the "carrier" and you've got the equivalent of AM overmodulation and it sounds bad! Turn down the RF gain and it is as though the "modulation" was turned back down so that you were back in the 50%-100% range and it sounds good. This is true on many, many radios that try to receive SSB on an envelope detector. Some are worse than others, usually due to attempts to minimize the impact of the BFO signal on the AGC by keeping the BFO injection as low as possible.

Subject: [R-390] 6BE6 SSB conversion

Hello, I just completed the V 505 conversion from a 6BA6 to a 6BE6. Actually, I used a 5750 tube. I'd be interested in anyone else's experience with this conversion. My observations are as follows. After the conversion, the circuit is definitely functioning as a product (heterodyne) detector. However, it was necessary for me to reduce the i.f. gain to well below the position it was at with the

diode detector configuration, to hear undistorted ssb signals. Is this to be expected in this modification? I hear plenty of signals with the i.f. gain reduced, but can no longer set the i.f. gain according to the directions seen on many of the R-390A websites, utilizing the line level meter. The signals seem to stand out on a nearly noiseless background. I have double checked the values of all components as well as the wiring. I haven't had time to take any measurements or retune the receiver. Perhaps this is the way it was intended to perform, but it is not quite what I expected. I thought I could just leave the i.f. gain where it was and crank the r.f. gain all the way up. I can leave the r.f. gain cranked with the i.f. reduced or I can set the i.f. gain where it was and reduce to r.f. gain and still hear all but the weakest stations. Any comments or suggestions would be greatly appreciated. Thanks very much.

=====
Here is the information that I was thinking of:

R-390A product detector mod - errata!

Stan, AK0B asked for feedback on the R-390A product detector mod (using a 6BE6 as a self-excited product detector) as first published in the 1/68 CQ and developed by Capt. Paul Lee, USN, W3JHR. There was also a knockoff of this design published in ER a year or two ago. Both detector designs, if built as published, WILL NOT WORK CORRECTLY! Both input excessive 455 kHz IF signal to the 6BE6; when built using the component values specified the detected audio will be distorted due to an overloaded 6BE6. The solution is to reduce the carrier input to the mixer tube. If using a 5 pf coupling capacitor to pin 6 of V506B as the IF signal pick-off as Capt. Lee suggests, then the resistor from the signal grid (pin 7) to ground of the 6BE6 must be greatly reduced in value from the 11 K specified value. I recommend a value from 1.2K to 2.7K. At 2.7K the detected audio from the product detector almost perfectly matches that of the AM diode detector (no apparent volume change on a zero-beat AM signal when detectors are switched). Using the lower value slightly reduces the detected SSB audio but it's extremely clean.

I'd also suggest those doing this mod consider switching the audio between detectors through the use of a tiny relay installed in the IF chassis switched by the existing front panel BFO switch; instead of replacing said switch and routing new audio wires over to it. This will also allow the subsequent swapping of IF chassis for test purposes. In my own receiver I used a half-wave rectifier & filter cap off the 6.3 volt line to provide DC for one coil lead of a small SPDT reed relay, the other lead is grounded to activate via the existing BFO-ON switch. Just clip the one wire at the switch that has continuous B+ on it (and heat shrink or tape well) and ground that terminal of the switch. This will provide a switchable ground back to

the IF chassis through the existing wire (instead of switched B+).

Never saw a subsequent errata msg. published in CQ or ER. Don't know why; I've had to fix three R-390As now where the user complained about raunchy SSB audio. Done correctly, the mod sounds great, is reversible, and is well worth doing.....

Subject: More-R390A product detector mod.

I neglected to mention on my previous post if one uses the switched audio relay option I suggested, the 6BE6 product detector/BFO will need to get its switched B+ via a second section of the added relay..... if a DPDT reed relay with adequate ratings can't be found, try finding a mil or commercial surplus miniature sealed can-style relay. Or, a small power MOSFET with a couple hundred volt rating could be used for the power switching function driven off the same switched low voltage B+ (haven't tried it myself - oughta work - will require some more R&D!)

Bill - de KD0HG/AAR8CC, ex WA9OZC

I hope it helps you. Craig

From: "George Blahun Jr." <ks1u@prodigy.net>
Subject: [R-390] 6BE6 SSB conversion

Hello. I was one of the people who benefited from Craig's forwarding of the information concerning the product detector mod. Initially I built the circuit using Capt. Lee's values but rebuilt it according to the ER article. In the rebuilt circuit which uses different values for nearly all components I ended up with a 3.3k ohm capacitor from pin 7 of the 6BE6 to ground. I found this value by temporarily wiring in a precision pot and tuning across the bands listening to ssb signals of greatly varying levels. The 3.3k value gives superb audio on even the strongest ssb signals. A value of 4.7k would give somewhat more audio but would produce a slight distortion on the strongest stations. I did use Capt. Lee's suggestion of a 1uf cap from the fast position on the AGC switch to ground and was pleased with those results. Prior to this modification I used the two small signal diodes added to the IF. I was never really satisfied with this mod and the product detector is really a very worthwhile project which I could probably duplicate (now knowing the errors in the original articles) in about 2 hours. The cost is also very reasonable, about 12 to 15 dollars.

Subject: Re: [R-390] TMC sideband converter

> Looking through the Feb. '63 QST, I see an as for a TMC SBC-1

These converters use a PLL circuit to lock onto the pilot carrier that was transmitted along with the ISB or DSB signal. The carrier doesn't have to be very loud as the converter can easily handle carrier suppressions of 10 dB or more. I have a CV-157 (that needs a little work) and it has a massive IF carrier pre-filter that's only a few 10s of Hz wide that helps to strip the carrier from the rest of the signal and improve the S/N ratio of the carrier going into the PLL. It also has another non-PLL detection mode which uses a hard-limited version of this filtered carrier signal as the LO (instead of the PLL generated signal); however when used in this mode it is not able to track a drifting signal. The spec for the PLL performance says that its PLL can track a signal drift rate of 10 cps/sec with less than 2 cps error.

The TMC units are more modern and were designed to replace the CV-157. From what I understand, one big improvement they made was to use a reactance tube to accomplish the VCO function required in the PLL circuit. The VCO in the CV-157 is made with a variable cap driven by a synchro motor through a precision 600:1 reduction gear assembly. The tube driver circuit for this synchro motor is direct-coupled and is quite elaborate in itself. Electric Radio #25 has the only write-up on a CV-157 that I've ever seen.

From: Nolan Lee <nlee@gs.verio.net>
Subject: Re: [R-390] TMC sideband converter

>Does anyone own & use one of these TMS SBC-1 units? How does it follow a drift signal?

The CV-157 SSB converter and the CV-116 FSK converters used gear reduction motor driven variable capacitors (one in the CV-157 and two in the CV-116). Once locked onto the carrier, the sets would tune the caps to follow the signal. Clever as hell. Both worked when they worked but were evil sombitches to fix when they puked. The CV-157 never really impressed me. BUT, the CV-116 and a pair of R-390A's (it had two input channels) would copy RTTY great. Both generated heat like mad. Come to think of it, both used the same cooling fan if I remember right. It needed to be about double the size they used. The one for the CV-116 faced upward and I think that the CV-157 faced out the back. The CV-116 was heavy but the CV-157 was about double. I'd guess 90 pounds. The CV-116 with it's five 6X4's is the primary reason that I can't stand the 6X4 even today. You couldn't keep standard 6X4's in it. The CV-157 used a pair of 5R4's and a couple of 6X4's and a big regulator tube. I don't remember all that many rectifier tube problems but the other 40 or so tubes were fun to replace. I scrapped my last CV-116 last year or so and have no plans to dig around looking for a CV-157. If one appeared at the next hamfest for next to nothing I'd throw it on the had truck and lug it home but if I had to ship one, forget it. ;-(

Subject: Re: [R-390] TMC sideband converter

>I have a CV-157 (that needs a little work)

I've never had one that only needed a "little" work. <grin>

>and it has a massive IF carrier pre-filter that's only a few 10s of Hz wide that helps to strip the carrier from the rest of the signal and improve the S/N ratio of the carrier going into the PLL.

Yep, I remember that. The CV-116 had about a half a dozen narrow bandwidth IF filter cans. I played with them with a signal generator and a scope. They were very selective but they were all designed for frequencies that nothing else used. I think I may still have a set in a box around here somewhere.

>It also has another non-PLL detection mode which uses a hard-limited version of this filtered carrier signal as the LO (instead of the PLL generated signal); however when used in this mode it is not able to track a drifting signal. The spec for the PLL performance says that its PLL can track a signal drift rate of 10 cps/sec with less than 2 cps error.

Not too shabby. :-) I didn't remember the other mode. It's been fifteen years since I had any. I'd have probably ignored that mode and used the auto tuning just to watch the dots spinning in the indicator window. <grin>

>The TMC units are more modern and were designed to replace the CV-157. From what I understand, one big improvement they made was to use a reactance tube to accomplish the VCO function required in the PLL circuit. The VCO in the CV-157 is made with a variable cap driven by a synchro motor through a precision 600:1 reduction gear assembly. The tube driver circuit for this synchro motor is direct-coupled and is quite elaborate in itself.

I remember that it had a serious reduction but I didn't know it was 600 to one.

>Electric Radio #25 has the only write-up on a CV-157 that I've ever seen.

Interesting, That's the first I've heard of them being written up on anywhere.

John, when you start on yours make sure that you test the tubes for gas. I found a lot a gassy tubes in both the CV-157's and the CV-116's. Maybe due to the heat, I don't know. And don't forget to oil the bushings in the fan. Pulling the AFC unit apart for a good cleaning and lube is a pain and tricky. Email me if you end up needing one of the motor driven AFC units for your CV-157. I think I've still got some good ones. They're hard as hell to find or at least they were 15 years ago.

Subject: [R-390] R-390A with product detector

I just picked up over the weekend an R-390A with a built in product detector. I have had many R-390's over the years, but I've never seen one like this before. There is a small plate, the same color as the rest of the panel, that covers the BFO Pitch and the BFO on-off switch. The top control says BFO Upper and Lower, and the bottom control says AM on one side and CW SSB on the other. I have not had time to take the receiver out of the cabinet yet, (yes I was fortunate to get it in it's original cabinet.) Has anyone seen this modification before? Is it a factory mod, or aftermarket? Any help would be appreciated.

From: DJED1@aol.com
Subject: Re: [R-390] SSB adapter

Yes, I've done that. I built a (ugh) solid state SSB adapter which feeds both audio and AVC back to the receiver. I take off the jumper between the diode load and the audio input, and feed the SSB audio into the receiver's audio through the input terminal. I built my adapter to provide the proper audio voltage levels, so your mileage may vary. I also included a switch segment so I can switch the receiver diode load back to the audio input, thus restoring normal operation for AM. It works great. I also fed the fast attack, slow decay AVC to the diversity terminal, so the receiver meter is operated by the SSB AVC. I don't think the PD-1 provides AVC. In that case, the simple diode mod is probably the best bet for really good SSB reception. Good luck with it.

Subject: Re: [R-390] Two dips on cap.

Jim you get two dips as the cap goes over center and there are two points where the cap has the same value each side of the max or min location. a normal thing. You will see this in the RF deck caps also. Some times one side or the other will be a bit better than the other side. Does any one have any good clues on getting a good null? I do not think my receiver nulls as good as I remember receivers did back in the 60's and 70's. Roger KC6TRU

Subject: [R-390] R-390A Extrenal Synchronous/SSB Detector

Need some advice and opinions from all you engineering types or otherwise out there. In the 1996 ARRL Hand book, page 15.33 there is a circuit for a synchronous AM detector for 455 Khz. I would like to know if anyone has built one, how does it perform and are there any known problems with it. From an engineering view does the circuit look right, are there any suggested improvements.

Are there any other circuits that do the same thing. I Would prefer not to go inside the R-390A to make changes. I installed the Dallas Lankford SSB Mod and it works quite well. A question on it's operation. For best performance the BFO has to be set to about -1 for LSB and -2 for USB. Is this normal? The BFO was adjusted for zero beat against WWV. CW seems normal and if anything works better than before the mod. This could be wishful thinking or hearing what you want to hear. The mod will removed when I get an external detector, purchased (PD-S1) or homebrewed.

From: "Scott, Barry (Clyde B)" <cbsscott@ingr.com>
Subject: RE: [R-390] R-390A Extrenal Synchronous/SSB Detector

Setting the BFO to zero beat on WWV at 12 o'clock isn't necessarily an indication that the BFO is adjusted correctly. At the 12 o'clock position, the BFO should be oscillating as close to 455kc as you can get it. I do this with a good frequency counter, but I suppose there are other ways to do it as well.

From: "Roger L Ruskowski" <rlruszkowski@west.raytheon.com>
Subject: Re: [R-390] R-390A Extrenal Synchronous/SSB Detector

Check the Motorola IC web pages. There are some synchronous AM detector for 455 Khz chips and audio chips available.

You can put it all together on a Radio Shack IC circuit board.

Pick up a transformer and bridge diode while shopping.

I like to hack dead PC power supplies into rebuilds. The box has the line filter, on off switch and power cord attached. Add a fuse holder, Use the caps from the dead power supply. Inductors too. This would power your new detector and Audio amplifier. Stick the bridge to the metal box for a heat sink.

Use the 455Khz out of the R390 /A. That's what it's there for.

I was looking a synchronous AM detector and found it in a single chip. The aplication notes with one of them had a complete test circuit. I was looking at a full receiver. The part cost retail price and feature analysis failed and the project was dropped as not profitable for a whole receiver.

Roger KC6TRU

P.S.

For limited production argravation exceeds return on investment. But, would you like to do a design to put a few chips on a Radio Shack proto board and develop a working proto kit and schematic for those inclined to build their own?

From: blw <ba.williams@home.com>
Subject: Re: [R-390] Ultimate BFO Zero Beat

If you are asking about using the BFO during reception, then you do set the BFO to zero for calibration. For receiving SSB signals, you set the BFO to a setting of half the filter setting you are using. In other words, if you are using the 4 kHz filter you should set the BFO to -2 for USB and +2 for LSB. This is per the -10 user's manual.

From: "AI2Q Alex" <ai2q@adelphia.net>

Subject: [R-390] R-390A SSB detector

I'm in the process of building an outboard solid-state product detector for my R-390A, if that's of any interest in this sync AM detector discussion. Yes, it can be done with tubes too; anybody got any 7360 sheet-beam deflection tubes laying around? I decided to use the old reliable Motorola MC1496 chip, which I've used successfully in the past as a doubly-balanced mixer and as a modulator in a homebrew QRP single-sideband transceiver. I have chatted with Ed, WB2LHI, about his circuit, which also uses the 1496. He supplied me with a Word file and schematic. His circuit gave me some food for thought, such as the use of a 28 V power source to get enough AGC voltage swing to be "plug-and-play" compatible with the '390. His AGC circuit provides a fast-attack, slow-decay AGC action. I expect to duplicate it. Ed uses a free-running BFO and buffer, but I've built up a crystal-controlled BFO instead (I had the rocks from an RT-718/KWM2-A). The xtals are diode-switched (and I use LEDs so I can see what I've selected from the front panel of my outboard adapter). The oscillator works fine, with a nice 2-V p-p sinewave output at either 456.3 kHz or 453.6 kHz. I anticipate dropping that level to 300 mV as per Motorola's spec sheet requirement for the LO port on the chip. The 1496 detector chip sub-circuit is almost finished, and I'll test that on the bench soon, so I hope to have a report on that shortly. So far, the chassis packs a transformer-operated full-wave power supply (the xfmr was pulled from a defunct "brick" or "wall wart" [the ol' Dremel tool was used to cut it open]), a 30-V regulator (an LM317), a 12-V regulator (a 7812), an ON/OFF toggle switch, power LED, BNC IF-in connector, RCA phono jacks for AGC-out and audio-out, a DPDT switch for AM/SSB selection, an SPST toggle switch for AGC time-constant selection, an SPST toggle switch for USB/LSB selection, a panel-mounted pot for IF level-set, and an internal pot for AGC level-set. I suspect the Philips NE602 or other improved mixer chips would also work, but I have the 1496s and the experience using them, so that's what I'm using.

Any thoughts? This project is under construction, so changes can be wrought as I see fit. Suggestions and comments are welcome.

Subject: Re: [R-390] R-390A SSB detector

The NE602 is far simpler to use than the 1496 because most of the '602 ports are already terminated internally and it doesn't need external balance adjustments. It is low power and therefore not great at handling really strong signals. 7360s never have been very common and are far less common now. They could be considered rare and very collectable, hence very expensive.

From: "Roger L Ruszkowski" <rlruszkowski@west.raytheon.com>

Subject: [R-390] R-390A External Synchronous/SSB Detector Planing 001

The NE and SA 602 variants and the NE and SA 612 variants are all good double balanced mixers formed on the Gilbert Cell design. I agree with Jerry the Motorola Chips are not as simple. But if Alex (see below) can debug a circuit that's easy to reproduce, then we could use that chip. Alex AI2Q, in Kennebunk, Maine has a 1496 detector coming alive on the bench. Last night I fired up the BFO buffer circuit, and routed its output into the mixer as well as a signal from my URM-25, and the mixer works. Got good audio output into my signal tracer. The packaging and AGC circuit continues. I'll keep you posted. Alex.

The 1st five chip plan from back to front.

Chip 5 an audio amplifier a LM (your choice .5 to 5 watt 8ohm output)

Chip 4 a NE / SA - 602 / 612 or 1496 double balanced mixer

Chip 3 an AGC IF amplifier between the input and the mixer

Chip 2 a PLL with switched LSB AM USB center free running values

Chip 1 an IF amp and limiter to develop a reference frequency.

Chip 1 accepts the IF signal and amplifies it until the level can be limited to provide a reference signal for the Phase Locked Loop (PLL).

Chip 2 is a PLL that in the absence of a reference signal (fade out of receiver signal) will free run at 455Khz. Three different oscillator tanks can be used. One tuned to 453 455 457. When a signal is present the loop would lock to the reference and drive the double balanced mixer with a good stable mixer signal of the exact frequency. On receiver signal fade the PLL would free run near the correct frequency. The two offset selections would let the SSB signal be centered in the narrower filter bandwidth of the receiver. With a good receiver signal the PLL output would be locked to the signal frequency and provide for synchronous detection. With a weak signal the PLL would loose lock and free run near the receiver signal and provide pseudo synchronous detection.

Chip 3 is an IF amp with an AGC circuit. This will accept the IF from the receiver and within the AGC range present the mixer with an optimum level of input signal.

Chip 4 is a double balanced mixer. One input is the AGC leveled IF signal. The second input is the PLL output. The output would be the synchronous detected audio.

Chip 5 is a stereo audio amp. One side is the audio out. The second channel would be used to produce the AGC voltage. This could be designed to also provide the AGC for the R390 if we want.

Lab experiment one will be wall wart powered. 455 IF coax input. Radio shack proto board mounted. In line DIP chips. Small speaker (4-8 ohm) output.

Nominations for chips is now open.

Subject: RE: [R-390] R-390A SSB detector

Thanks Ron, but I don't have the resources to do that. I'm strictly a homebrewer! By the way, as per your suggestion, I looked at the PD-1 product from Electric Radio. It's nice that they provide the schematic for the box. However, it seems to me to sidestep too much of the R-390A's existing circuitry. Also, it makes no provision for AGC, for example, and the on-board op-amp used as an audio output stage looks too meager for my taste. Also, why use the 1496 chip as an AM detector when there's a perfectly good one in the existing radio? Food for thought.

Subject: Re: [R-390] R-390A External Synchronous/SSB Detector Planing 001

Except that its impedances are around 50 ohms, the SBL-1 double balanced mixer from MCL is even simpler to use than the NE-602 and has far better dynamic range. Once the PLL locks to the incoming carrier (and it is noise sensitive unless the VCO has narrow range and very good stability), because there's usually a 90 degree phase angle required between the carrier and the VCO, there's a need for a 90 degree phase shift to the AM detector to recover AM. Otherwise you will be recovering the PM of the signal. Precise 90 degree phase shifts are a pain to produce. I think I prefer a narrow filter to the limiting amplifier for carrier isolation. A limiter can't tell the difference between carrier and tones (e.g. music) in the sidebands or in interference.

There also has to be some sort of low pass filter after the detector to keep BFO leakage and IF leakage out of the audio amplifier.

Except for carrier lock, the receiver boards by KK7B already have everything but AGC built in. Sold by Kanga, I think.

There are possible alternatives, though they may involve more complexity and not just plug onto the receiver. One is a fixed frequency BFO, (crystal for stability), and the PLL moves the receiver LO to affect lock. The TMC receiver out in the garage did that, though when it wasn't trying for pseudo synchronous detection, it had a PLL to lock the LO to a slightly dirty mixed crystal reference synthesizer, so it used alternate phase detectors for different applications. Or the synchronous detector could have an additional IF at some frequency other than 455 Khz and the mixer oscillator for that conversion could be warped.

I've not seen the recent ARRL handbook circuit.

AGC is a real problem because of the frequency dependent propagation effects on AM signals. Controlling by amplitude of carrier can be wrong, controlling by recovered audio doesn't allow for modulation level changes according to the program material, controlling by power level in the IF bandpass can be wrong due to interference. Probably there needs to be a combination of AGC sources. Perhaps the peak value of the carrier or each sideband independently.

There were some very good references on synchronous detection (mostly applied to DSB reduced carrier) in the December 1956 issue of the Proceedings of the IRE, an issue on SSB.

Subject: [R-390] Possible R390A SSB Discovery

Was talking to fellow RF guru Jim Walker up in Stowe, Ohio this evening about a couple of R390A problems he was having. We worked through them and he happened to mention that he and Noland had some Clevite mechanical filters. Clevite was one of the (4?) contractors who built filters used in the R390A which include: Collins, Dittmore-Friemuth, White Water Labs and Clevite. (Did I miss one Les? Who did the crystal filters I hear about?)

I digress.... Together, I think Jim and I may, and I emphasize MAY, have come up with an important discovery: there may be some R390A receivers out there that were intentionally designed to receive true SSB without an external converter. I suspect it would be a random retrofit v/s a specific build as we would see some different small run order numbers popping up.

Recently, Jim had tested several of the Clevite filters and found them not to be resonant on 455kc but on 458. (feel free to add to this Jim, if you are "listening"). Help me out here list, I am not an SSB theorist, but wouldn't the carrier oscillator

frequency or BFO injection frequency of a receiver using a 455kc IF be tuned to 458kc in order to receive upper sideband?

In as much as the military uses USB almost universally, it would make sense that if an R390A variant were designed to truly operate on SSB, it might have the SSB module I have pictured on the WWW site >plus< a suite of ASYMETRICAL (for SSB v/s SYMETRICAL for AM) Collins mechanical filters installed?

Those of you who have asked me "how well do R390A's work on SSB?" Get the standard answer, "not real well, they are (each one I have ever come across, anyway) equipped with symmetrical mechanical filters designed for AM. Yes, you can inject the BFO at increased levels, make the Captain Lee (?) mod (help me on that one Les, I always forget his name despite it being discussed in old issues of The Hollow-State News in detail) that R390A's lack one very important component for effective SSB work, ASYMETRICAL IF filters. Thus, IMHO they are sub-standard SSB receivers, blah, blah, blah.....

Indeed, Collins factory part number tables assembled by the Collins Collectors Association do describe 2 types of filters for A3 emission for many of their receivers and transmitters. The symmetrical for AM reception is assigned one part number and the asymmetrical for SSB another.

Jim and I agree that to find one filter on 458 kc means only that you have a filter resonant on an "incorrect" frequency suggests more than simple coincidence.

Thanks to Jim's phone call to me tonight, together, we informally pieced this puzzle into something that might fit together with regard to this SSB business.

This will give Tom and Les a new tangent to head off on.

Just goes to show you, once you think you've heard it all, something else pops up.

Subject: Re: [R-390] Possible R390A SSB Discovery

Any connection to the Clevite ceramic filters that were used on a short run (we think) of '60 EAC's? Or is that just a coincidence, i.e. Clevite did mechanical filters as well? Are there any date clues on the receivers you've seen like this, particularly on components that may have been subbed when the alternate filters were installed?

> Recently, Jim had tested several of the Cleve filters and found them not
> to be resonant on 455kc but on 458. (feel free to add to this Jim, if you are

Anything special about how the filters are marked? Maybe we have to start
compiling filter part numbers to make sense of it. I suppose some pilgrims might
have trouble aligning units that were converted. Would this affect alignment, or
would you just do the standard stagger tuned job, etc.?

. Help me out here list, I am not an SSB theorist, but
> wouldn't the carrier oscillator frequency or BFO injection frequency of a

Of course, the part nos. wouldn't correspond to what you found there, right?
That would be too easy, unless something was embedded in the numbers, like
"458" vs "455". That would also be too easy I suppose.

>

> Jim and I agree that to find one filter on 458 kc means only that you

condicence.

Only one of the four? There was a thread on aging filters going off spec. from the
uh, I guess, vibration. Are they like some resistors which all have a tendency to
drift upwards over time? I guess there's no sign of a marking or aluminum self
adhesive label in the bandwidth switch area? Which one of the filters is 458? --
same position on both receivers? 'know what I'm drivin' at? Of course, what I'm
doin' is like "carrying coals to Newcastle", as you have probably seen the innards
of more R-390A's than practically anybody.

> Thanks to Jims phone call to me tonight, together, we informally
> pieced this puzzle into something that might fit together with regard to this SSB
business.

Isn't use of the phone cheating? ;-)

> This will give Tom and Les a new tangent to head off on.

Yup. Actually, tracking down to module level would be the next stage -- if
someone really wanted to. That answers the depot dog issue as well.
Reconstruction by original whole radio contract tells us what was so originally, but
there was a long road after that with on site module swapping, wholesale
overhauling at the depots, etc. So, tags don't mean much, as we've learned, and
neither do the markings on the back panel, when available -- as far as identifying
what we have now. Of course, some might say that'd be picking the flyspecks out
of the pepper shaker, but, hey, it's like the mountain climber who climbs mountains
"because they're there".

> Just goes to show you, once you think you've heard it all, something else pops
up.

The late "Rosanadannadanna" said it best .. "If it's not one thing, it's another thing,
and if it's not that, it's something else, and" While we're on the subject of
"something else", I've posted before on another modification that I'm looking for
information on. Probably not related to this filter question, but the general situation
might suggest something. I have three A's which all came from the same source
on the West Coast. They all have regular R-390A tags, all depot dogs, but dogs-
with-a-difference. They have extra self adhesive stickers saying "R-1980" and
"Contains TMC Mod Kit #375" on their front panels. There's a small metal box on
the back panel, partly covering the Xtal Osc. adjustment access hole, which
contains a pc board with SS components -- an IC or two included, as I recall --
sporting two BNC's and one MB connector. Two additional bnc jacks are added to
the back panel itself. There are several MB - T-connectors tapping into various
points, plus a small metal box under the xtal calibrator which elevates it up to the
level of the cutout in the Utah cover. The PTO is definitely involved and it looks

like at least part of the mod was supposed to hook up to an external frequency counter (or two), but there are about 5 extra connections all together. Possibly a delta frequency setup to interpret the counts? But also possible for some injection of some external stuff, I guess. What relevance, you ask? These three were in a master crate of surplused out radios along with 4-5 others like them. They had been in storage for at least 8 years. Components seem to range from '60 to '67 -- all mixed, refinished front panels, mixed tags, etc. As if they were taken fresh from depot overhaul for installation of the TMC #375 kit. The "R-1981" sounds like something somebody made up on the fly -- probably in 1981. Soooo. after that shaggy dog story -- and these are a bit shaggy, tho' 2 of three work so far -- If the 458 kc thing was actually a mod, then it probably was done in batches, probably at the depot level and possibly right after refurb. There should be some tell-tale somewhere. However, if the mod was limited to the IF deck, it could have been handled as an on site module swap-out. Even so (the dead horse is still moving), I'd think the module would have a marking somewhere it could be seen by a tech doing an alignment -- sticker or stamp on the filter cover or whatever. It's probably too late to lift fingerprints.

Motorola also made mechanical filters. Not sure i know anything about who manufactured the x-tal filters. Chuck, that sounds reasonable to me. Jim and I spoke about this very problem about 1-1/2 weeks ago. I just figured he had a bad filter when he mentioned only one peak. Yes, it was Captain Lee...of course there have been offshoots and variations of his original modification.

I have always thought that the agc characteristics of the R-390A were poor even for am listening. The Lankford/Chambers agc/ssb mod corrects this problem much easier than Captain Lee's mod. The attack and decay times for all three positions, slow, med and fast need to be speeded up. The Lankford/Chambers mod does this.

From: blw <ba.williams@home.com>
Subject: Re: [R-390] Possible R390A SSB Discovery

Thanks for deepening the mystery of my TMC #375 kit radio too! I've asked for many years about that tag and nobody seems to know a thing...until you just mentioned it too. That got me curious, and I went and looked at the back. Sure enough, there's 2 small holes drilled into the chassis just left and above the xtal osc adjustment hole. Sure looks like a box would partially cover the adjustment hole if those holes were near the corners of a box like you describe. The other 2 holes are to the right under the IF output jack- so the box would have been oblong. Also, there are 2 mystery BNC jacks. One is between the IF output and unbalanced antenna connector. The other is above the F101 fuse with a stick on label stating, ERROR J1104. The other jack has glue remains where a label was stuck on at one time. There are no marks on the clean chassis where a can cover might have sat for a while. There is no sign of another box under the xtal calibrator like you mentioned. That extra unmarked BNC plug is not hooked up to anything. The extra BNC plug marked ERROR J1104 has a mini coax cable going to the VFO subchassis with a locally made dynamo tag saying, CA 480-1174-17. It goes to the VFO subchassis right next to V701. I can see it going into a grommated hole between the Cosmos and the S701 wire bundle. That's about all I can see for now.

I'll go ahead and mention the other curious things about that radio just in case it sounds familiar, or to just dump more oddities into the mix. That radio was bought for me by a friend of mine at the Dayton Fest, probably around 1994, but before 1995 for sure. It was mint clean, and I mean clean enough to eat off of. The wire bundles sparkled. All of the cans, decks, chassis, you name it, was clean to the bare metal. It looked like it just rolled out of the factory. No dust on the tops of resistors behind the front panel or in the switches. It had to be mothballed in some way. There was no lube at all on any of the gears. It was a dog for performance though. No sensitivity below 8 mHz. Calibration points off or almost inaudible. USB inoperative below 8 mHz unless the 16 kHz filter is selected. I never did much work on it other than swap tubes several times and letting it run for weeks to cook. Cleaned the antenna relay. I never had time to do much else.

We had a discussion on the 67 EAC on the list some time back, and that got me curious on that radio. It was tagged as a Stewart-Warner. The chassis is clearly marked as a 67 EAC. The AF deck is EAC, as well as the power supply. The RF and IF decks are identical in workmanship, markings, sheen, etc and I'll bet anything they are EAC components as well. I'll know when I take them out soon. Has a new Cosmos PTO. I ended up swapping tags with someone on the list who had a 67 EAC tag and wanted the S-W with contract # just like I had. Got lucky on that one.

Let me know what you find about about your batch of radios. This is all very interesting. I didn't find any place where a R-1980 tag could have been. There is a bit of old glue where the freq cards normally were at, but nothing else. There is all evidence this was not a depot dog, but a radio manufactured and then left bagged somewhere for years. No scratches or marks where work was done on it. No rubs or normal dings. The front tag is the only odd thing when looking at all of the radio and the impression you get from it.

Hope you find out more on these radios. I was puzzled by this one, but I'm really curious after reading about your 3 radios.

Subject: Re: [R-390] Possible R390A SSB Discovery

The talk of symmetrical vs asymmetrical filters for SSB reminded me of an old Collins mechanical filter catalog from the seventies that I have. There have two types of filters listed as Chuck mentions. The symmetrical ones are like what is in the 390's. These can be used to receive SSB by placing the carrier or BFO about 20 db down on either side of the filter passband depending on which sideband you want to receive. Thus by using one filter and two BFO oscillators both USB

and LSB can be received. This type of filter work fine in this application as witnessed by all of the Collins S-Line and A-Line equipment and that of many other manufacturers. The so called asymmetrical or sideband filters are still symmetrical filters (by the shape of their pasband shown in the Collins catalog) but the center frequency of the filter is offset to the point of where the BFO frequency would be if a single filter was being used. In this configuration two filters and one BFO oscillator is required to receive both USB and LSB.

This system is used in the Collins 51S-1 and later commercial receivers. By using the two filter system one is able to detect Independent Sideband transmissions where two different signals are transmitted, one on each side band. To receive ISB the receiver also needs to have two separate IF, detector and audio systems after each filter. By putting the BFO frequency some 20 db down the filter passband makes both types of filters asymmetrical with respect to the desired signal because the carrier or BFO is the reference point.

In my opinion, and that's all it is, the 390A doesn't do well at receiving SSB not because of the filters but because of the AGC design in the receiver and the lack of a product detector. I believe the attack time of the AGC is too slow and the delay needs some adjusting. To a large degree this is what the Langford AGC mod addresses.

A product detector is the correct way to demodulate a SSB signal. As to Chuck's possible discovery of a SSB 390 with a filter having a center frequency of 458 KC for USB is entirely possible. In the S-Line difference between the filter center frequency and the two BFO frequencies is 1.35 KC In the 51S-1 the difference between the 500 KC BFO oscillator and the center frequencies of the two filters is about 1.5 KC.

The 3 KC difference that Jim and Chuck discussed may seem a bit large but the frequency difference is a function of the filter bandwidth. Hopefully this was of interest to someone, but if not there is always the delete key....

From: "Roger L Ruszkowski" <rlruszkowski@west.raytheon.com>
Subject: [R-390] External Synchronous/SSB Detector 002

Once upon a time the NE561 and SA561 PLL were in production as the one chip AM synchronous detector solution. If we can find these still in production it would be a way to go for about \$3.00 each. These are 26 - 30 volt devices.

A \$15.00 Five chip solution is as follows.
NE604 IF Amp and limiter.
NE562 PLL operating at 1,820,000 hertz (4 x 455)
CD4013 Dual D flip-flop /4 90 degree quadrature signal from PLL
NE602 Double balanced Phase Modulator.
LM 384 5 watt audio amp.

The NE 604 RF section is used as an AGC stage to provide a more uniform (within AGC range) level of signal into the detector. The limiter section is used to provide a limited reference for the PLL.

The PLL would provide a constant out to the detector. On signal fade the PLL offers a better circuit than the changing level of the input signal. The down side is the PLL set up at 90 degree out of phase with the signal. So we run the PLL at four times the 455Khz and then divided it by 4 back down to the necessary 455. the flip-flop gives us the 90 degree shift we need between the PLL and the signal. The PLL should also free run near the 455 AM 453 LSB or 457 USB to provide a better output with weak signals.

The CD4013 is a Cmos 7474 dual D flip-flop. The CMOS just fits with the voltage levels of the NE logic chips better than the five volt level of the TTL chips.

The NE602 is the double balanced demodulator.

The LM384 with 5 watts should be ample audio output.

Now to do a schematic so we can build a circuit for testing.

Subject: Re: [R-390] External Synchronous/SSB Detector 002

I tried to use a NE561 or 560 more than 20 years ago to "clean" up noise on a WWVB signal at 60 KHz. The quality of the VCO was so bad it took a slightly noisy signal and left it as a very badly buzz modulated signal. The 560 family chips looked like they'd do a lot better than they did. As a practical matter, the VCO would need to be made practically crystal controlled to be a useful receiver accessory.

The CD-4013 making a quadrature signal will have more error than you can allow because of delays inconsistent at rise and fall and output port and still have decent side band rejection. The propagation time is too variable. something in a 74F or 74HC might be consistent enough. Been there tried that too.

The 56x family mostly will run at 26 to 30 volts maximum but will work adequately at lower, like maybe 12, and converting to TLL level isn't a great problem.

Subject: [R-390] USS Albacore radio room restoration R-1051 progress

Well, I got my 1496-based LSB/USB adapter off the bench and connected to my R-390A, so the ol' workbench was freed up for the next project, the USS

Albacore's radio room restoration.

By the way, the SSB adapter works great. It makes it *very, very* easy to tune SSB, and the AGC action is fine. I do have a defective pot in the limiter of my R-390A, and that's causing some hum, but if I can get a replacement pot, I'm sure that problem will be resolved (does anyone have a limiter pot/switch assy. for sale or trade?)

If you want to really see how well a -390A plays on SSB, I encourage you to build up a product detector! Thanks to WB2LHI, Ed for his ideas and encouragement on the product detector circuitry. His uses a free-running BFO; mine uses 456.3 kc. and 453.6 kc. xtals, but either way is fine. It doesn't have to be rockbound to be stable. <snip>

Subject: [R-390] BFO position and SSB

Recently, there was a thread about where to set the BFO for proper SSB reception. It is known that setting the BFO to approximately -1.5 for USB and +1.5 for LSB is the correct thing to do as it places the signal in the center of the passband of the filters.

I began to wonder if there was something wrong with the IF alignment, though, as I could place the BFO virtually anywhere between -2 and +2 and still hear SSB by adjusting the kc as needed. I found out last night, though, that there is indeed an audible difference where the BFO is positioned.

I selected a nice, clear, 75M LSB roundtable discussion (a very enjoyable discussion of loop antennae, feeder stubs, etc.) and placed the BFO at +1.5. The signal was nice and clear. I then put the BFO at zero and retuned the signal with the kc adjust. Sure enough, I was able to hear a slight distortion as part of the signal fell outside the passband. Going back to +1.5 and retuning and the signal was very clean again. It takes a good, clear, signal to hear it, but it is definitely different. Using this method, I found I could even select the 0.1kc filter position and still get a fairly intelligible signal.

It is amazing at how "present" SSB sounds in the R390A, even though it has no product detector. I prefer listening to it rather than my TS440S/AT. Somehow, it just sounds better.

Probably not anything in this message that most don't already know, but I didn't have anymore good boyhood danger stories to share although I did try to make gunpowder one time. It didn't work. I suppose it's a good thing, though, as the quantity I was playing with would have precluded me from sharing my story with the living. Sign me as another happy R390A customer...

Subject: RE: [R-390] Possible R390A SSB Discovery

Go to http://www.logsa.army.mil/etms/find_etm.cfm and look for:

R-1981:
TM 11-5895-288-35 AN/TSC-20,AN/TSC-20A,AN/TSC-25 (2.1Mb)
TM 11-5895-288-24P AN/TSC-25 (16.8Mb)

One of these TM's had a few pictures of the modifications you described below. This was for a R-1981 not a R-1980. I don't know what the difference is. The TSC-20, TSC 20A and TSC-25 use some sort of SSB RTTY decoder that must monitor and control the oscillators in the R390A to maintain a decoder signal lock. Thanks to Dave Merrill for the link and R-1981, R725 TM numbers.

Subject: Re: [R-390] Possible R390A SSB Discovery

Barry,

Thanks for deepening the mystery of my TMC #375 kit radio too! I've asked for many years about that tag and nobody seems to know a thing...until you just mentioned it too. That got me curious, and I went and looked at the back. Sure enough, there's 2 small holes drilled into the chassis just left and above the xtal osc adjustment hole. Sure looks like a box would partially cover the adjustment hole if those holes were near the corners of a box like you describe. The other 2 holes are to the right under the IF output jack- so the box would have been oblong. Also, there are 2 mystery BNC jacks. One is between the IF output and unbalanced antenna connector. The other is above the F101 fuse with a stick on label stating, ERROR J1104. The other jack has glue remains where a label was stuck on at one time. There are no marks on the clean chassis where a can cover might have sat for a while. There is no sign of another box under the xtal calibrator like you mentioned. That extra unmarked BNC plug is not hooked up to anything. The extra BNC plug marked ERROR J1104 has a mini coax cable going to the VFO subchassis with a locally made dynamo tag saying, CA 480-1174-17. It goes to the VFO subchassis right next to V701. I can see it going into a grommeted

hole between the Cosmos and the S701 wire bundle. That's about all I can see for now.

I'll go ahead and mention the other curious things about that radio just in case it sounds familiar, or to just dump more oddities into the mix. That radio was bought for me by a friend of mine at the Dayton Fest, probably around 1994, but before 1995 for sure. It was mint clean, and I mean clean enough to eat off of. The wire bundles sparkled. All of the cans, decks, chassis, you name it, was clean to the bare metal. It looked like it just rolled out of the factory. No dust on the tops of resistors behind the front panel or in the switches. It had to be mothballed in some way. There was no lube at all on any of the gears. It was a dog for performance though. No sensitivity below 8 mHz. Calibration points off or almost inaudible. USB inoperative below 8 mHz unless the 16 kHz filter is selected. I never did much work on it other than swap tubes several times and letting it run for weeks to cook. Cleaned the antenna relay. I never had time to do much else.

We had a discussion on the 67 EAC on the list some time back, and that got me curious on that radio. It was tagged as a Stewart-Warner. The chassis is clearly marked as a 67 EAC. The AF deck is EAC, as well as the power supply. The RF and IF decks are identical in workmanship, markings, sheen, etc and I'll bet anything they are EAC components as well. I'll know when I take them out soon. Has a new Cosmos PTO. I ended up swapping tags with someone on the list who had a 67 EAC tag and wanted the S-W with contract # just like I had. Got lucky on that one.

Let me know what you find about about your batch of radios. This is all very interesting. I didn't find any place where a R-1980 tag could have been. There is a bit of old glue where the freq cards normally were at, but nothing else. There is all evidence this was not a depot dog, but a radio manufactured and then left bagged somewhere for years. No scratches or marks where work was done on it. No rubs or normal dings. The front tag is the only odd thing when looking at all of the radio and the impression you get from it.

Hope you find out more on these radios. I was puzzled by this one, but I'm really curious after reading about your 3 radios.

Barry (another Barry)

> I have three A's which all came from the same source on the West Coast.

> They all have regular R-390A tags, all depot dogs, but dogs-with-a-difference.

They have extra self adhesive stickers saying "R-1980" and "Contains TMC Mod Kit #375" on their front panels. There's a small metal box on the back panel, partly covering the Xtal Osc. adjustment access hole, which contains a pc board with SS components -- an IC or two included, as I recall -- sporting two BNC's and one MB connector. Two additional bnc jacks are added to the back panel itself. There are several MB - T-connectors tapping into various points, plus a small metal box under the xtal calibrator which elevates it up to the level of the cutout in the Utah cover. The PTO is definitely involved and it looks like at least part of the mod was

supposed to hook up to an external frequency counter (or two), but there are about 5 extra connections all together. Possibly a delta frequency setup to interpret the counts? But also possible for some injection of some external stuff, I guess.

>

> What relevance, you ask? These three were in a master crate of surplussed out radios along with 4-5 others like them. They had been in storage for at least 8 years. Components seem to range from '60 to '67 -- all mixed, refinished front panels, mixed tags, etc. As if they were taken fresh from depot overhaul for installation of the TMC #375 kit. The "R-1981" sounds like something somebody made up on the fly -- probably in 1981.

>> Soooo. after that shaggy dog story -- and these are a bit shaggy, tho' 2 of three work so far -- Barry

Subject: Re: [R-390] BFO and other stuff

Maybe I am missing something here...have we forgotten just what a "sideband" is? It is the "product" of the carrier frequency and the modulation frequency, which is why it is best decoded with a..."product detector" ??? If I modulate a 4000 KC carrier with a pure 10KC tone, and then remove the carrier component of the signal, I will have only two frequencies at which energy is present... 3990 KC and 4010 KC. These are the lower and upper "sidebands", and if I remove the lower component, it means that my receiver must be tuned to BEST receive energy at 4010 KC. This means that I would have to DROP my BFO frequency by 10 KC to have it "beat" with the non-existent or suppressed carrier. If all I was going to do was receiver 10 KC tones from people rude enough to transmit them, this would be an excellent way to tune my receiver, in fact, if it weren't for the fact that my detector and audio path can't really do much with it, you could even receive that signal with 100 Hz selectivity as long as it was dead on. But in real life you have speech, and practical speech communication limits wasted energy over 2 or 3 Kc that adds little to the intelligence, and most of the energy falls more in the 100 hz to 2500hz range. Music requires a bit more, but almost nobody (except for pirates, maybe) is intentionally using more than the 10Kc of bandwidth customary in AM

broadcast, and it is more like 8 Kc or less. So to receive your pipe organ and cymbal ensemble broadcast on USB, you would want to dial your selectivity to 8 Kc and tune four Kc above the carrier frequency, and offset the BFO down 4 Kc. BUT...If you decided to use 16 Kc selectivity, YOU WOULD NOT crank your tuning up another 4 Kc and your BFO down to minus eight (if it were possible)...because the signal is still topping out at 8 Kc.

The main tuning and corresponding BFO offset tuning should be in the amount of the AVERAGE MODULATION frequency of the received signal... period.

If you want to receive highly compressed voice modulation such as aircraft communications which fall between about 500 and 2000 hz, you're going to want the tuning and BFO offset to be .5 Kc to 1 kc regardless where you choose to crank the selectivity setting. All that opening the bandwidth up will do is allow more adjacent channel interference, and cranking it down will just roll off the lower and higher audio response.

Or am I wrong? Maybe I haven't the slightest idea what I am talking about...

From: Jack Antonio <dia@dia.reno.nv.us>
Subject: Re: [R-390] BFO and other stuff

I don't think you are missing anything at all, we are actually talking the same language here! For discussion let's assume that the receiver is set up perfectly, the filters are all exactly centered on 455, the BFO calibration is on the money with zero at 455, and that the filters have perfect selectivity(that is their skirts are straight up and down). First, on your 10 kc tone on a 4000 kc carrier, let us assume it is a perfect USB transmitter. If you tuned your receiver to 4000 kc at 16kc selectivity setting with the BFO at zero, you would not know a signal is there, because the 16kc filter will not pass any signal more than 8 kc from the center frequency. But if you tune your receiver up 2kc in frequency, then the 4010 sideband will be just at the upper edge of the filter bandwidth, and now if you tune the BFO down 2 kc to compensate, you will have your 10 kc sine wave at the diode load terminals. Whether or not you hear it in the speaker or headphones will be dependent on the response of the audio channel in the radio. Note that your receiver dial is now saying 4002, the BFO says -2, which means your (suppressed) carrier is 4000.

The only way to recover the original 10kc tone with a selectivity of .1 would be to tune the receiver to 4010, then offset the BFO 10kc.

But you are right, we don't listen too much to 10 kc tones. If we are listening to music, on a USB transmitter, with an 8kc upper limit, then the selectivity should be at 8, and the BFO at -4. This will demodulate audio from the transmitter from 0 to 8000 cycles(if the transmitter has that frequency response). Opening the selectivity to 16 would only open the door to off channel noise and signals.

BUT, if our USB transmitter was transmitting audio with a bandwidth of 16kc, then we would have to set the selectivity to 16, and offset the BFO by -8. The fact that we can't do that on an R-390 is simply because the Army didn't consider that to be a requirement. In fact the 390s were designed to recover signals approaching 16 kc bandwidth like multichannel teletype, and voice, but only with an external converter.

Your statement about offsetting the tuning and BFO by the average modulation amount is right on the money, and if the transmitter had a lower modulation limit of 0 cycles and an upper limit of our receivers selectivity setting, then your statement and my statement agree perfectly. But if the transmitters frequency response is say 300 to 2300, then the selectivity should be at 2 and the offset should be -1.3kc, which is the average of 300 and 2300 cycles.

But, we don't know the frequency response of the transmitter, the filters aren't exactly on frequency, the BFO calibration isn't perfect, filter skirts aren't straight up and down and humans are much more adept at dealing with whole numbers than dealing with adding and subtracting numbers like 1.3.

So, I stand by my statement. Set the BFO at half the selectivity mentally compensate for the offset when tuning in, and once you have found your signal, use the tuning, selectivity and BFO controls to optimize the signal for its modulation characteristics, and noise and interference present. For SSB, 2kc is a little narrow, 4 kc is a little wide, so for general tuning and listening, I use the 4kc setting, dropping to 2 when the conditions warrant.

This is what sets the R-390 and its kin from lesser receivers, the fact that we can adjust these things in a stable repeatable manner.

I hope I haven't bothered anyone with this post, and if I'm in error anywhere please let me know about it!

Subject: RE: [R-390] BFO and other stuff

I'd like to add a comment that nobody has mentioned. For optimum SSB reception on an R-390A when not fitted with a product detector, advance the audio gain pot all the way, and then adjust overall gain with the RF gain pot (caution: there's no AGC action if you do this).

For CW reception,
I like to set the BFO offset for single-signal reception, and main tuning for desired tone. No use hearing the same sig either side of zero beat!

From: blw <ba.williams@home.com>
Subject: Re: [R-390] BFO and other stuff

I experimented with various combinations of BFO settings, selectivity settings, and offset tuning. I always get the best audio and sensitivity when doing it the way the manual says. Maybe it's just my radio, or maybe mine is working right and someone else's isn't. I've tried all sorts of ways and the standard method always works the best for my PH-56.

Sometimes the audio improves greatly by opening up the selectivity and making necessary offset adjustments. There is a lot of wideband AM out there. I usually use the BFO with AM signals at first, and if it's strong enough I turn off the BFO and see if the signal is good enough then. Getting centered on a weak AM signal is easier for me if I first note the right frequency with the BFO and then turn it off. I then tune down or up to center tune it without the BFO. This works better for me too if there is co-station interference. Using the BFO is the best way to find a weak carrier because there are lots of times you aren't going to hear anything at all when you turn it off.

There is no correct or right solution for tuning FM stations as far as I know. There have been a few pirate FM stations in the past, and if you don't know it's in FM mode it will drive you nuts trying to figure it out. You end up thinking the radio has gone crazy since nothing works like it used to. Sometimes, the BFO will get it. Sometimes the BFO won't work at all. There is no rule to getting a good FM signal. Well, there is one rule. There is a razor thin margin in getting an FM signal. It takes a lot of fine tuning before you get it, but you can.

Subject: [R-390] AM-SSB/CW Demodulator homebrew schematic

I have on my homepage a page for my "new" R-390A/URR, but it is still under construction. On this page there are 2 pictures (front and inside) from the homebrew AM-SSB/CW demodulator with ZF preamplifier, BFO, S-meter circuit, included power supply and NF stage.

I was asked by some people if I have the schematic diagram for this unit.

This unit was built 10 years ago as a 455 kHz demodulator (I had no R-390A at this time) and I was not able to find the schematic for it. After a long search I found a hand drawn (really !) schematic for the part IF preamp, AM-SSB/CW demodulator BFO and S-Meter amplifier. The NF stage and the power supply (solid state :-(((and the voltage stabilizing part with a OA2 is not included, its common.

The R-390A page is not really ready for view, because it contains only some

pictures of my Steward-Warner (all parts of it, exclusiv the filters and the PTO which are from Collins) are original Steward Warner and the receiver is unmodified. I have not recaped anything but will do it for the "killer-capacitor". But I have scanned the hand made schematic and have made a download link under the picture of the demodulator unit to a ZIP file named SSB1.zip that contains a JPG file with a resolution of 100 dpi and a TIF file with a resolution of 300 dpi for printing.

You can find this page under:

<http://www.swl.net/oe1002419> (NOT under the Austrian web page address !!).

Please look the 1st page that opens, click on Enter and in the left frame that shows up, under "Receivers" you find a link "Steward-Warner R-390A/URR" . Click on this link and you come to the 390A page. In the middle of the page under the picture of the demodulator unit you find a link. Click on it and you can download the zipped files.

If you have any troubles with it, please let me know. I think it could be of some interest for some of you. Please let me know what you think about it. It is possible, that there are not all values in the scheatic really totally exact, as I said, it was built 10 yeras ago and the schematic was drawn last week.

From: "Dr. Gerald N. Johnson, electrical engineer" <geraldj@ames.net>
Subject: Re: [R-390] BFO and other stuff

Copying FM on an AM receiver can be difficult. It can be accomplished with two methods, providing the FM is narrow. Slope detection requires an IF passband with some slope, at least as much as the occupied bandwidth of the FM. That's not available in the 390 or 390a which is made to have a relatively flat bandpass with steep slopes.

The other technique that works for truly narrow FM is exalted carrier. Just like listening to AM with the BFO on. Set the receiver for SSB and zero beat the carrier. Truly narrow FM has the same amplitude spectrum as AM, just the relative phase

of carrier and side bands is different (in phase for AM, 90 degrees out of phase for FM). Received with the exalted carrier method, truly narrow FM can sound better than SSB. Used to run that on 2m in the Dallas Texas area in the mid 60s. W5WXV probably did it for a lot longer than I did.

From: Meir Ben-Dror <mbendror@optonline.net>
Subject: RE: [R-390] R-1247/GRC-129, is this it? (name correction)

This equipment was part of the GRC-129 system which had 2 R-1247/GRC-129 (modified R-390A) receivers. The system was a high-stability diversity system. The mods on the R-390A's were done by Manson Labs, which manufactured the associated equipment listed below. Some synthesizers were made by Hallicrafters, too under contract. I don't know whether Halli was the first designer of the synthesizers for the system or Manson. because the sideband converter is switchable between 2 receivers (A and B). The receiver was modified to accept inputs from the external frequency synthesizers which generated all the necessary LO frequencies. The receiver in this version has small relay boxes by the LO in/out cables/plugs which switch over from internal to external LO operation. The IF output was utilized through an SSB converter (2 channel) which provided the demodulated audio output (the BFO was supplied externally from one of the synthesizers). The CV-1693 is the 1 MHz step synthesizer and the O-1203 is the 1 KHz step synthesizer locked to the same frequency standard. With the 2 synthesizers the receiver is tunable within its normal frequency range in 1 KHz steps. The frequency still has to be dialed in the receiver, because the RF stages and mixers have to be peaked up at the frequency of operation. The receiver can

be operated normally, too. I also had another part of the same system which is not built by Manson, (at least my unit), the O-1555/URC which is a synthesizer to set the frequency of a modified T-368 transmitter whose GRC-129 nomenclature eludes me. The component I never had is the SSB generator. I also had some documentation on the synthesizers. I used to have the major components of the GRC-129 system - I still have the receiver which works normally by itself - it has 2 tags: the system tag - R-1247/GRC-129 Receiver, Manson Labs S/N 48, contract # AF30(635)30962; and the original R-390A tag: R-390A/URR, S/N 1832, Motorola, contract 14-PH-56.

Here is the list of the rest of the GRC-129 components I sold a couple of years ago (with documentation):

1. CV-1694/GRC-129 Converter, Single Sideband, Manson Labs S/N 61, contract # AF30(635)30962.
2. CV-1693/GRC-129 Synthesizer, Electrical, Frequency, Manson Labs S/N 89, contract # AF30(635)30962.
3. O-1203/GRC-129 Synthesizer, Electrical, Frequency, Manson Labs S/N 89, contract # AF30(635)30962.

From: "Roger L Ruskowski" <rlruszkowski@west.raytheon.com>
Subject: Re: [R-390] BFO

There should be a stop washer under the BFO knob on the front panel. The knob should set close enough to the front panel so the knob stop will engage the stop washer. This should let you have about 270 degree rotation of + - 3KC of BFO. If you move the Knob forward to clear the stop or the stop is missing, you can get several rotations from the shaft and a whole range of frequency. At the end of the BFO travel you will feel a snug stop.

Do not force this as it will break your BFO coil in the can. Check your flex coupler under the IF deck. The BFO should go end to end with out undue stress on the coupler compression or expansion. At 455Khz the coupler should be at minimum compression or expansion. The BFO shaft changes length out side the can with rotation ie its a threaded bolt.

Normal is to set Zero knob pointer to 455. Then learn where USB and LSB are on your receiver. This is a relative knob location varying with band width, alignment of RF and yada yada yada YMMV. Some people like to set zero where their choice station / mode / band / bandwidth demodulates well. Then they learn where to set the knob when they try to zero the PTO against the cal tones.

As long as you are not forcing it you are ok. Check the IF deck shaft bushing and front panel bushing for good alignment. This will go a long ways to make the BFO

shaft operation smooth and easy.

You should get from 452 (-3) to 458 (+3) KHz out of the BFO. You will get more. YMMV it will not be exactly the same spread both side of 455 but it will be close. i e you may not see any because of the not exact stop action.

Subject: [R-390] SSB product detector schematic

The solid-state product detector I've been working on is debugged. It works so well that I almost couldn't tear myself away from my R-390A last night. It just sounds so good. In fact, I have antenna relays connected so that I can switch back and forth A-B style between my Ten-Tec Omni-V and the '390A. The R-390A receives every bit as well as the Omni-V, although the selectivity of the T-T is a bit better. Nonetheless, it's a great pleasure to listen to the full and well-rounded audio of the '390A. It's really pleasing to listen to. I was copying V51AS (weak signal) and 3C1AG (weak, buried in noise) on CW and lots of SSB stations on 160 and 20 meters--all with ease and outstanding clarity and presence, and with nice AGC action. If I try to copy SSB or CW using the 390A's BFO alone, it's okay--but the product detector makes a VERY BIG world of difference. I urge list readers to dupe the circuit, and have therefore drawn the schematic of my circuit in the hopes that some of you will homebrew it.

The circuit is based, in large part, on the work of Ed, WB2LHI. His diagram shows a free-running BFO. Mine is crystal-controlled. I adopted his 28 V AGC scheme and it works great. I copied the 1496 chip's connections directly from the Motorola datasheet's suggested connections. The only thing I did not do was capacitively couple the output of the 1496 to the AF level pot. I may add that over the weekend; it should isolate the pot's action--but the chip works fine with the configuration I'm presently using.

I also employ some LEDs in my xtal switching circuit. That makes for a fancy front panel that tells me which rock is selected. I'll eventually label the LEDs on the panel. You can see this in my schematic. The diode-switched xtal oscillator gilds the lily a bit, so you can use hard switching if you want to live a simpler life.

The schematic is scanned in two sheets (two files). I'd be happy to send these files to anyone who wants them in the following formats:

- (1) OrCAD
- (2) .BMP
- (3) .TIF
- (4) .GIF
- (5) .PDF

I am also willing to fax the prints to anyone CONUS who needs them, as long as

it's during the weekdays when my fax machine is on line.

I'm also willing to mail them via US Snail to whomever will send me an SASE to my callbook address. Vy 73, AI2Q, Alex in Kennebunk, Maine .-.-.

From: "AI2Q Alex" <ai2q@adelphia.net>
Subject: [R-390] Product Detector Notes

The response from the R-390A folks on the list for my schematics has been almost overwhelming. So far, I've satisfied almost 100 requests for files and will also be FAXing drawings tomorrow. I hope I didn't miss anyone, but REV B drawings show all the LEDS backwards! I must've been in a late-night Zener-diode state of mind when I drew the original schematics. My latest REV C drawings correct my mistake, showing the LEDS properly forward-biased, as they are in my actual circuit. If you have REV B files, and want REV C files, just let me know and I'll send them. I had a number of queries as to where I got the 455 kc crystals. Mine were FSN replacement parts for an RT-718, which you likely know as the KWM-2A. I've had them in my junkbox in their original MIL wrappers for quite some time after purchasing them at a flea market. I wouldn't know where to get more, but there have to be sources. Also, it may be possible to find 455 kHz crystals and "rubber" them onto frequency with variable padder/trimmer capacitors. If anyone can find a source for more crystals, or wants to see if a crystal manufacturer might be willing to supply some, perhaps a group buy can be arranged. Also, two R-390 list members said they were going to convert my files into router files for circuit board layout. Is there anyone who might be willing to fabricate boards if there's enough interest in the R-390A group?

Subject: RE: [R-390] SSB product detector schematic

That's correct Mark. I originally had that that way, and later pulled the LM317 because I needed it in another socket on another project (!), so I substituted a pass xstr and a Zener diode. I guess I simply assumed (you know about that word), that a builder would recognize that i "simplified" the regulator part of the schematic.

I'll post this to the list so others can benefit from your "catch."

Stay resonant es 73, AI2Q, Alex .-..

Date: Mon, 5 Feb 2001 19:14:53 -0500
From: "AI2Q Alex" <ai2q@adelphia.net>
Subject: [R-390] Product detector notes

(1) Gosh Bill, I didn't even look at the part number for the xstr. I just pulled it outta my junkbox and soldered it in. I assume it's got about the same gain (beta) as a NPN 2N2222.

(2) Small-signal transistors aren't too critical in audio circuits, or even at 455 kc. You may want to look through Rat Shack's shelves, or an ECG catalog to find one that suits your liking. The X29A829 types that I have here work well. They carry an ECG159 equivalent p/n.

(3) The 1496 chips are still available (I think Dan's Small Parts stocks them). I've used old Fairchild uA1496s in projects (in TO-5 cans), and Motorola 1496 chips (in DIP packages), and I think Signetics made them too in DIPs. A Web search might reveal other vendors.

Good luck, and let the group know how you make out. Perhaps someone else will dupe the circuit with a different Gilbert-cell chip (refer to the ARRL Handbook). There's nothing magic about these devices.

(4) One other thing: for the LC circuit, I pulled an old IF-type coil from my junkbox and measured its inductance and Q (it's Q is about 80) on my old 1950s-vintage Heathkit Q-meter. Once I knew that, I used an ARRL Lightning Calculator and determined what capacitance would be needed to resonate it at 455 kc.

Next, I placed the parallel LC circuit in series with a resistor and the output of my URM-25 signal generator. Then I placed a scope across the resistor. At resonance it exhibits a high impedance and the current in the series resistor drops, so the voltage across it drops and I adjust the coil for a null on my scope. You can also place a low-C scope probe directly across the LC combo and adjust for a maximum voltage at anti-resonance, but I prefer keeping my probe off the actual circuit and measuring indirectly, so to speak, at the resistor. At 455 kc, it doesn't much matter which way you approach that, but I guess the way I do it is a matter of how I was trained. :-)

All you need do is ensure that it resonates at about 455 kHz, and that the coil's adjustment gives enough range to tweak it a bit above and below that. You can also use a variable capacitor, such as a compression trimmer, across the coil, in order to get some adjustment.

Once in the circuit, I adjusted the coil's slug coil for best sinewave shape. It isn't a

pure sinewave, but the FET buffer and small-value coupling caps keep the loading on the oscillator light. If you load the xtal oscillator too much, you won't see much of what should at least resemble a sinewave, but judging by the TTL oscillator that's used in the Electric Radio Model PD-1 accessory, it seems like the 1496 might not be too "choosy" about waveshape anyway. My discussion's with WB2LHI, Ed, confirm these observations. By the way, my process of selecting low value coupling caps, and choosing a FET with its high input impedance and low output impedance in a source-follower circuit is the same process Ed used in developing his circuit, and I borrowed heavily from his notebook.

(5) For assembly, I use "ugly" construction techniques. One of the best is called Manhattan construction. Check out <http://www.qsl.net/k8iqy/socket.html> for some tips on this very useful technique. Using it, you can build and tear down and re-vamp circuits quickly, building and testing them in modules, rather than all at once. -- AI2Q, Alex

Thanks for the correct files. Just curious - is there a way to print them out with black print with the normal white paper background?? The way I printed them out with the traces in white with the black background sure does eat up the black ink cartridge! If anyone decides to make a board available I am good for a few.

What is the complete part number and source for the 1496 chip and what # has worked for you in the "pnp" small transistor category? In the 60's when I repaired KWM2s I had several sets of xtals and the matching mech filter - now - where did I put them???!?

Subject: [R-390] SSB circuit diagrams available

AI2Q Alex <ai2q@adelphia.net> designed a fairly simple SSB circuit based on the
Motorola MC1496 chip. Technical questions should be directed to either Alex or
to these lists, as I haven't built the circuit yet. I volunteered to put the circuit
diagrams up on my web site, which I have done. I also put a lot of time in trying to
find the best compromise between size and print quality. There are two .PDF files
(black on white, and white on black), .GIF, .TIF, and .JPG files available for each of
the two schematic sheets. I recommend the first .PDF file (black on white, fairly
compact). The best resolution is the two .TIF files (but they are large at around
250K each). They are all located at my website: <[http://www.pdq.com/
boatanchors/ssb/](http://www.pdq.com/boatanchors/ssb/)>

Any feedback that I get I'll try and incorporate into the web page. Information
about vendor sources, printed circuit cards, component sources, and so on, I'll be
happy to include, as well as builder reports (problems and successes!).

The parent folder (boatanchors) is far from complete, so don't expect to find
anything useful there - thanks!

Subject: [R-390] Connection of CV-591 to R-390

I just brought home a CV-591A, and it's working well with my R-390 so far. Can someone tell me how the CV-591 connects into the R-390 to allow the AGC developed in the CV-591 to be used in the R-390? Are there any other connections between the receivers recommended other than IF to the CV-591 and AGC to the R-390?

Date: Sun, 26 Aug 2001 02:10:38 -0400
From: Thomas W Leiper <twleiper@juno.com>
Subject: Re: [R-390] Connection of CV-591 to R-390

There is only one connection, and that is the IF. The CV-591 has its own internal AGC amp which seems to have excellent range and performance without the need to modulate the R-390*. I usually just set the R-390 to MED agc with the RF gain at max and use SLOW agc on the '591 for perfect SSB. All the extra connections on the CV-591 are for two different levels of line audio and a remote control head.

Subject: [R-390] Variant of a Variant

Thank you to all who took the time not only to take a look at my R-390A pics (at <http://kg6zi.homestead.com>), but also to write with your best wishes and comments. What I gather so far is this: Several have mentioned the Factory SSB info on Chuck Rippels's website. That example uses a 6EA8 in a module located in the same place as the one in my receiver. The IF strips seem to be similar in that each has a cable coming from under the chassis to the same place on topside.

A couple of differences: My radio uses a 6U8 instead of the 'EA8. (This threw me until I realized they are very similar tubes.) Another is that the crystals in the Ripple example are mounted on top of the sub assembly and are below in my example. So it seems I have a variant of a "rare" variant? Maybe its only a cosmetic variant. Anybody know how many of these (generally, not just my just 6U8 example) exist?

I'm sure a circuit tracing exercise would tell me lots of things, but in any event....A couple of questions arise in my mind:

1. To what extent is this "mod" documented? I found no reference to it in the Y2K manual. Is this simply a crystal controlled BFO to provide more appropriate injection levels for SSB reception?

2. What other modifications may have been made in conjunction with this one to improve SSB reception? For example, AGC mods or other changes to the IF strip.

As I dwell on my prior usage of this radio, I recall not being very impressed with SSB on it. Reading other material here leads me to believe that I'll be spending some quality time with the AGC system to address those symptoms. I would REALLY like to know how what I am looking at (in terms of voltage and resistance readings, for example) might be different from the manual due to the nature of the variant and not due to component failure. I'm sure to follow more than my share of dead end troubleshooting trails as it is without throwing that one into the mix...)

As always, I look forward to your collective wisdom.

Subject: [R-390] Lankford AGC Mod ?

I understand the Lankford AGC mod to be two diodes in the AGC circuit and a cap change to allow more BFO insertion into the detector. I understand what happens when we inject more BFO into the mixer (detector) circuit. I do not understand how the diode mod causes the difference we do hear in single side bans signals.

How does that circuit work?

What is the difference in AGC action of the circuit?

Why does SSB sound better with the change?

What caps should we experiment with to give better time constances?

What would be some target values for those caps?

Other than exceeding the PIV or forward current load of the diodes does the

choice of diode make a difference?

Is diode linearity critical for this circuit?

Is diode switching time critical for this circuit?

I know this is all available some where. Does some one have it handy and can you send me some clues.

Hi Gang, did a while back... Just the diodes and immediately noticed distortion on strong AM broadcast signals. Removed and All is Well. What the hey.... If you want SSB turn on your Ham Rig or if your an SWL just reduce the RF gain like in the old days. My .0002 cents worth

From: DJED1@aol.com
Date: Fri, 11 Jan 2002 18:58:20 EST
Subject: Re: [R-390] Lankford AGC Mod ?

The only thing the diodes do is to shorten the attack time of the AVC to give the "fast attack, slow decay" AVC that we want for SSB. On AM, the carrier is there all the time and the attack of the AVC does not have to be fast. Since all activity is at voice rates, the diodes do not have to be especially fast to perform satisfactorily. I expect any good silicon diodes will do, as long as they have a high resistance when back biased.

From: DJED1@aol.com

Subject: Re: [R-390] Lankford AGC Mod ?
To: cbscott@ingr.com, r-390@mailman.qth.net

The AVC is half of the problem with SSB on the R-390s; the other half is the product detector. I would estimate that fixing the AVC is the most important part, because to detector in the radio does OK if you just reduce the IF signal enough.

The classic way to do this is to go to manual gain control, and reduce the IF signal enough to have the detector operate in a linear manner. As we know, the SSB signals sound pretty good when the radio is operated in manual mode. So... I believe much of the problem is caused by the fact that the AVC doesn't respond fast enough to the varying SSB signal, resulting in distortion at the detector. The Lankford mod just allows the AVC to increase quickly by changing the attack time constant (it basically shorts the timing resistors in one current direction). Similarly, an audio AVC will help the fast attack requirement. I went the whole way and built an external adapter which provides both product detection and fast AVC- works quite well except my BFO is not nearly as stable as the internal one. Hope this helps... Ed

Subject: [R-390] PD-1 SSB reception, AM effects

I just got a PD-1, the outboard product detector sold by Ron Haskins. Nice, professional looking unit, construction very tidy internally. No brainer hook up, just patch cord off IF output on back apron, plug it in, and go. The SSB is wonderful, very simple. Might be nice to have slightly finer tuning on the KC dial to fine tune voice pitch, but overall, it is really nice. The down side is that it tends to overload just slightly on very strong AM signals. I am talking about signals that peg the carrier needle. I am running it through an Alpha Delta VRC console, basically an amplified speaker with notch, peak, variable freq. response, etc. Its possible that the two don't work well together. I am going to hook it up to an outboard stereo amp and check that. I thought perhaps I had a problem in my AGC, so will sub out the three tubes, one by one, and see if that might help as well. Its interesting that the Lankford mod seems to have the same AM problem. I will keep you updated.

Date: Sun, 13 Jan 2002 13:04:35 -0700

I was just looking at the CV-591 and it looks nothing like my Eldico SBA-1. It's a little unclear what the controls are on the front panel of the CV-591, except for the obvious ones. The SBA-1 has a notch filter, a noise limiter, and an IF gain, in addition to the usual SSB, audio, and power controls. I am really curious what the

military nomenclature might be for my unit it has Signal Corp stamps on it so there must be one. The search continues.

With all thus talk about SSB, I remind you that a circuit for a product detector I built still resides at <http://pdq.com/boatanchors/ssb/> as well as at <http://fly.hiwaay.net/~wb7vdn/Download.htm>

Also, I recently glommed an old Hammarlund HC-10 box, and have it connected to

my 51J-4, although it will work with my R-390 or -390A as well. It's input can be quickly adjusted to accept IFs from about 430 kc to 510 kc.

I stabilized the free-running BFO in the HC-10 with some high voltage Zener diodes (in series), and replaced the 5Y3 with diodes to offload the filament demand on the power xfmr.

The HC-10 does a pretty good job on SSB. It's kind of fun to have a set with two IF strips, detectors, AGC lines, filters, limiters, and audio stages.

Subject: Re: [R-390] CE Sideband Slicer
Date: Thu, 21 Feb 2002 23:13:42 -0700

The Signal slicer (SS) is not a receive sideband adapter it is designed to give SSB to any of a number of AM transmitters. These are phasing rigs and with proper adjustment put out some of the best sounding SSB phone on the air. I have a CE 10B exciter which incorporates the SS with a 6 watt driver section I have had it on the air running through My Heathkit SB-200 which gives me about 65 watts using a monitor scope to adjust the wave form, fabulous sound.

Subject: Re: [R-390] CE Sideband Slicer

>The Signal slicer (SS) is not a receive sideband adapter it is designed
>to give SSB to any of a number of AM transmitters.

You mean the "Sideband Adapter". The CE "Sideband Slicer" is indeed a receiving adapter. It operates on the phasing principle with an IF input frequency of about 455 k. The phasing network must be present for it to work.. if that is missing you can duplicate it but it takes components of moderate precision (1%). Other than that, the circuitry is not complicated or hard to understand. The accessory input preamplifier is not normally needed, especially with the R-390 that has plenty of voltage at the IF output. I can't tell you how well it works because the one I have here it not working right. 'Dont' know why yet.

Subject: [R-390] Sync Detect Results

Well, I had little to do today as will soon be apparent. I went ahead and made an IF cable for the 390A, and made a coupler out of a piece of foil about the size of the Sony radio, and connected same to the cable. I sat the Sony on the foil to pick up the IF signal. I then connected the Sony's line-out to my regular amp.

Results were excellent.

The Sony locked no problem while sitting on the 455 coupling foil. In fact the signal was so strong it still locked three feet away, so the 390A is putting out gobs of 455 IF. The coupling contraption needn't be very large. The sound through the amp is good from the line out, although I'm sure the Sony could use some audio optimization. You can really tell the difference between the fading on the headphones and the reduction of same through the amp. Lock range is about 3-4 kcs. Allows you to tune around QRM, and select the best sideband. The filters in the 390A are naturally still effective. Radio New Zealand on 17675 will be the test subject tonight.

Subject: [R-390] Sync Detect Radio w/R-390A [warning sand word used in text]

Gentlemen? What is the best way to couple the 455 for best S/N??
Pontifications welcome. Great weekend to all!! Tom N5OFF

The 455 output in the IF deck starts as a 50 ohm source from the cathode follower. The deck to back panel is 50 ohm connectors and 50 ohm coax.

I would carry that 50 ohms source from the R390 into the new sync detector box. In side there I would go for a transformer match to the higher input impedance of the detector circuit. Even if it is sand state the input will be more than 50 ohms. I would go for a tuned IF deck transformer and work the winding ratio to get close.

If you can not rework the transformer, Then find a load resistor for the secondary that lets the most power be transfered over to load resistor. This is where the voltage across the load resistor is largest and the transformer will peak up a good 455 signal and by definition let out of band noise be passed to ground.

An inter stage IF that matched 5-10 K plate to a 1 meg grid would only match the 50 ohm up to 5 - 50 K. OK for a bipolar transistor. But still low for a FET or tube. Then you couple off the load resistor with a small cap to the still higher input impedance of the first active device. The small cap and high impedance then looks like a scope probe monitoring the signal at the load point.

Cheap broad band method would be as follows. If the detector input is real high (tube grid / FET) then you terminate the 50 ohm coax into a 50 ohm resistor at the detector end and couple the signal into the device through a small cap. Terminating the signal into a good load keeps trash on the signal line (distortion SWR noise) down. The small cap and high impedance then looks like a scope probe monitoring the signal at the load point.

Could we pull the 5814 Diode detector, and replace it with a sync detector plug in 9 pin thing. I forget what the other 1/2 of the 5814 does. A FET could go in to function as that triode. Roger KC6TRU

Subject: [R-390] Synchronous AM Reception

Having just recently got my R-390A back out of storage, I find myself interested in MW DX'ing again. I have re-read two articles on modifying the R-390A to acheive carrier synchronous demodulation, and was wondering if anyone has any experience with it, and if it is worth attempting:

An NRC reprint from 1992 uses:

- a coil of wire around the anode of V508
- 100K (or 47K) resistor
- a 5-50 pf trimmer grounded to the carrier meter adjust nut
- a 47K (or 22K) resistor in series and connected to pin socket 1 of V505

Once it's set up, how do you use it, what effects do you observe.

From: "Tom M." <courir26@yahoo.com>
Subject: Re: [R-390] Synchronous AM Reception

I've never used that method, but it sounds to easy to be true. Seems like a true sync detector needs to measure and actively alter the BFO frequency needed to keep things straight. The best way is to use a Sherwood SE-III or similar device, but they are expensive and are getting hard to find. I made a poor boy hookup recently, using a Sony portable with sync detect for a detector, tuning it to 455 khz, couple the IF signal to it with a whort wire nearby, and then route the line output to an amp. Worked well on a 390A and also on a 51J3 (500 kcs IF). Gives you selectable sideband sync detection in a small box with little fuss. I already had the radio. You can probably get a Sony 2010 or 7600G?? on ebay. There is a kit out there offered by Steve Johnson, and the ARRL handbook has a homebrew detector. Bonne chance!

From: David Wise <David_Wise@Phoenix.com>
Subject: RE: [R-390] Synchronous AM Reception
Date: Fri, 22 Mar 2002 11:49:08 -0800

A sync detector needs to control the BFO slowly and continuously, so in between dropouts it remains at least approximately on frequency. I don't think the NRC mod's worth trying. Judging from your description, it's more like a synchrodyne* detector than a true synchronous. The latter contains a PLL, locked onto the IF. The NRC mod locks the BFO to the IF (via "pulling", usually a problem, here used intentionally), but only when there's signal. On every little dropout it will instantly revert to its free-running frequency. The synchronous detector's PLL drifts too, but so slowly it doesn't make a beat note during most dropouts.

* Uses amplified, amplitude-clipped IF as BFO into a product detector.

If you can't find an SE-3 for a price you're willing to pay, Tom's recommendation holds. Use any sync-detector-equipped radio that can tune your IF. Once in a while you can find one really cheap because it has a blown front-end. It might still pick up the R-390A's _loud_ IF output.

Subject: Re: [R-390] Synchronous AM Reception

Hello, What is synchronous detection and how is it different from zero beating the BFO against the carrier?

Date: Fri, 22 Mar 2002 17:45:14 -0800 (PST)
From: John Kolb <jlkolb@cts.com>
Subject: Re: [R-390] Synchronous AM Reception

Sync detection is mainly for AM or DSB, not for SSB. With sync detection, the supplied BFO signal is phase locked to be exactly in phase with where the carrier should be. During selective fading, or with DSB, the carrier is weak, missing, or phase shifted from where it should be. With the BFO in phase with where the carrier should be, the highest possible audio output results. If the BFO is 90 degrees out of phase with the carrier, cancelation occurs and no signal is heard. That's the deep fades in the audio you get with the BFO on when receiving an AM station, and almost but not quite zero beat.

In the book "New Sideband Handbook" by Don Stoner W6TNS. published by Cowan Publishinh Corp. Fouth Printing March 1962 (The publisher of the CQ Radio Amateur, on pages 128 to 132 is a very interesting article about Synchronous Detection.

From: "Jim Amos" <jimamos@cisco.com>
Subject: RE: [R-390] Synchronous AM Reception
Date: Mon, 25 Mar 2002 15:58:14 -0500

There was also a circuit in the 1999? handbook that was both a synchronus detector and external BFO / product detector. It did use a 455KHz IF input as well. This circuit was nice in that it also provided for synchrodyne demodulation. This is a version of synchronous detection that amplifies and limits the carrier before applying to the product detector. It does not, however, phase lock a carrier generator to the incoming signal as true sync detection does. Interesting for comparison, however.

The drawback to this circuit is that some of the IC's were not as readily available as one would like. I'm working on a version that should be completed some time before the 75'th B'day of my R-390A that uses NTE available IC's. But this project is still in the planning stages and is a result of the following failure:

I was recently experimenting with a circuit originally published in Comm. Quarterly based on a Motorola Stereo Demodulation chip. It however, it not go well. The version of chips that I received would not lock over a wide enough range to make the circuit useful as an add on Sync Detector.

I also have a friend that was selling synchronous detector kits. His kits were based off of the IC used in the Sony receivers. They worked quite well, and provided for sideband selection of the AM signal. They were purely for AM demod however, and did not provide a SSB / CW product detector.

From: John Kolb <jlkolb@cts.com>
Subject: Re: [R-390] Product detector rocks - USB/LSB rocks

Well, \$35 a pair isn't much better than \$20 each for the 453.5 and 456.5 at INRAD, although the 453.6 and 456.3 would be a better match to the 2.0 kHz filter of the R-390. This isn't an application that requires xtal stability - I'd go for either two LC tuned circuits - this would let you adjust the BFO freq relative to the mech filter edge to get the voice sound you prefer - or a large BFO tuning knob like on the CV-591, with an adjustable oscillator circuit tuning 455 +/- 3 kHz. I've got some 455.0 kHz xtals if anyone has need of one. Work great if you have a matched pair of LSB/USB mechanical filters.

Subject: Re: [R-390] SSB reception with R-390A

My set came with the Paul Lee mod. It works well - but is too extensive and may be the cause of a change in AVC behaviour. I would have left the set alone and used an external SSB converter out of choice. Preferably a CV-591, but no chance of getting one of those here. Would have done my own using tr*ns*st*rs and ch*ps.

From: "Drew Papanek" <drewmaster813@hotmail.com>
Date: Fri, 01 Nov 2002 17:04:30 -0500
Subject: [R-390] SSB Reception with R-390A

My vote for SSB reception is the 2 diode (Lankford) modification for its simplicity. This method works quite well. A couple of points:

1. Make sure that AGC capacitors are not leaky, especially the large oil filled unit atop IF deck (This should not be a problem for Bruce as his receiver was done by Rick Mish)
2. When increasing BFO injection capacitance remember to adjust BFO

neutralization in AGC IF amp.

The 2 diode modification gives good SSB reception even without altering BFO injection. Done this way and with AGC capacitors verified leak-free (by Dr. Jerry's method) I have not found any change to reception of AM and CW signals strong or weak.

Capt. Paul Lee's 6BE6 product detector modification has been mentioned. The National NC-300 uses a 6BE6 as a product detector giving good results; this should perform satisfactorily in the R-390A (although the NC-300's final IF is 85 KHz vs R-390A at 455 KHz). Lee's R-390A mod calls for alteration of mainframe wiring harness to run shielded audio cables to a multisection BFO switch. This accounts for some of the "invasiveness" of the mod.

I would suggest leaving mainframe wiring and BFO switch intact and use a small relay in IF module for audio switching. The relay would be powered by B+ switched to the BFO-turned-product detector when in SSB/CW mode. A quick perusal of Mouser's catalog shows a 24V relay with coil power consumption of 70 mW. A series dropping resistor to operate this relay from the (approx.) 180V B+ line would dissipate only 450 mW. In this fashion modification would be limited to IF module only.

The diode bridge is sold by Rick Mish, and it has been written about in ER. It is also shown on page 89 of Viappiani's book (in Italian) about the 390A. If you don't have Viappiani's book, I recommend it. It has A LOT of good stuff. Of course it IS in Italian, but most of the circuits are in English. And those that aren't, I've been able to figure out what is going on. The heart of this SSB module is a traditional bridge circuit of 4 diodes (probably 4148's). The (+) lead goes to term. 16, the ground on the R-390A. One AC leg goes to terminal 13 of the line audio out. The other AC leg has a 600 to 10K ohm resistor (just which value is chosen I don't know) in series with it, between the AC leg and terminal 10 of the line audio out. The (-) of the bridge is connected to terminal 4 of the AGC. All terminals are those found on the back of the R-390A. I have a couple of these "modules" and have not found them to be any improvement over just using standard settings for listening to SSB on a R-390A. I've recently acquired a CV-591A, and the one I have isn't that much better either. Of course, YMMV.

From: "Tom M." <courir26@yahoo.com>
Subject: Re: [R-390] SSB Converters Diode Bridge

All you need is a \$.99 Radio Shack full wave bridge rectifier. If you've got a junker power supply lying around, there is likely a capable bridge in it ready to use. Refer to the back of the RS package. Route your line audio to the two AC inputs of the part, ground the + pin and wire the - pin to your AGC terminal.

When copying SSB, you simply crank in a little line audio to provide additional AGC action to the set. You may also wire in a little resistance to your liking. When

listening to AM, turn your line audio to min. Elegant. Wish I'd have thunk of it. Back in the day, some guy was charging good money for this Cracker Jack prize, selling it as a sophisticated gadget.

From: federico.baldi@virgilio.it
Subject: Re: [R-390] SSB Converters

Yesterday evening (late evening) I was in wrong when I spoke of Diode Load, but Tom here describe the scheme and connections of the diode bridge very well. In my experience (I put this little circuits on both my R-390A/URR) you must set the receiver controls as follows:

Line Meter : + 10
Line Gain : 7-8
AGC : slow or medium
Bandwidth : 2, 1, 0.1 kHz as needed
BFO Pitch : as needed +/- 1
BFO : on
RF GAIN : 10
Function : AGC
Local Gain : for desired volume

You must tune in an SSB signal, line level meter should read 50-75 on audio peaks, you can regulate Line Gain if you put Line Gain to 0 the adapter is turned off, in other words this has the same effect as removing the adapter from receiver. Try, no risk, very low cost, good results (you shall judge), you don't need to regulate RF Gain thereafter. In my personal opinion the SSB converter is a nice object but don't add anything to the results that you can get with this circuits that worth 4 USD maximum (including your time). Federico

P.S. : I agree with Tom an all.

From: Bob Camp <ham@cq.nu>
Subject: Re: RE: [R-390] SSB Converters Diode Bridge

Germanium would not be a good idea here. The idea is to have a diode that goes high impedance when reverse biased and low impedance when forward biased. More or less you are using it like a switch rather than a detector. A germanium diode does not go as high impedance when reverse biased as a silicon part. If you have 1N4148's they should do just fine. Last time I saw them they cost less than a dime each.

Subject: RE: [R-390] SSB Converters Diode Bridge
Date: Tue, 14 Jan 2003 22:20:21 -0600

Not sure it is clear to everybody that the diode bridge to AGC is NOT an SSB converter in the same sense as a product detector and BFO. What it does is use the audio level to run the AGC to get better control of the audio volume level because there is no carrier for the original AM based AGC. You still have to tune the R390 very carefully for best reception.

Subject: [R-390] Re:R390(A) - S.S.B.

Years ago, for a special project at the University of Idaho where I work, I added a fairly easily removed mod to an R-390 wherein I used 1/2 of the 12AX7 (IIRC) which fed the IF out to the jack on the back, as a triode product detector. The detector circuit I used, the same circuit used in Heathkit's SB/HW transceivers, actually looks more like an "infinite impedance detector" than a true product detector as such, since it seemed to work equally well for AM as for SSB. In any case, it was much quieter than the diode detector and was pretty effective.

The mod took very few parts, worked quite well, and was easily removed if you wanted to. I didn't bother with changing the AGC time constant. I just kept the RF gain down a bit, and ran the audio gain up. I had used the same circuit back in the 1960s in another R-390 we were using as the receiver for 'phone patching for the troops in Vietnam and Thailand when I was in AFMARS, and in a BC-779 which I used for RTTY. I've never liked the 6BE6 for anything since it is so noisy. The only mixer tube I know of which was noisier was the 6K8/12K8, but I think there are noisier tubes than those. Rambling.....

Subject: [R-390] Resistors, SSB

I have found the 2 diode (Lankford) modification to be extremely effective for SSB reception on the R-390A. The addition of these diodes is not an alteration to the detector as some might suspect. Instead, diodes are used to shunt 2 AGC time constant determining resistors. The result is a short negative going time constant (fast attack) and the original positive going time constant (slow decay). Fast attack enables AGC to capture signal peaks and slow decay "remembers" (for a short time) those peaks so that gain is appropriate for future peaks. Result is a tolerable signal to BFO ratio at the detector (minimizes distortion). That time constant alteration accounts for most of the mod's effectiveness.

The Lankford modification also increases BFO coupling cap for more injection, and adds capacitance to AGC line. The mod works well without these capacitor changes.

For good AGC action on all modes using medium and slow AGC switch settings verify that the 2 uF oil filled AGC cap is not electrically leaky. <snip>

From: Jim Brannigan <jbrannig@optonline.net>
Subject: [R-390] CV-591

Thanks for the comments on the CV-591 and the R-390A. The CV-591 was swapped for an SBA-1 and most of the SSB peak distortion went away. So I dug into the AGC and IF AMP. circuits on the CV-591, replaced a few components and now it is "playing" much better. There is a 10mfd. oil filled CAP in the audio circuit that might also need replacing. This is the first time that I used the Eldico SBA-1 with the R-390A and it is interesting.

The SBA-1 has crystal controlled oscillators and a crystal filter, so the R-390A must be run wide open (8 or 16MC. filter). It also has an IF gain control, notch filter, noise clipper and a BIG S-meter that is fun to watch. The filter in the SBA-1 is better than the '591 filter, so running wide open is not a problem. I'm not sure which one I prefer.

From: "Drew Papanek" <drewmaster813@hotmail.com>
Date: Fri, 17 Jan 2003 17:22:18 -0500
Subject: [R-390] CV-591

With R-390A bandwidth wide open it is possible for strong signals within R-390A passband but outside of Eldico passband to desense the R-390A via AGC action (if R-390A generated AGC is enabled) or R-390A IFOverload (if AGC is taken from Eldico and fed back to R-390A). You could close up R-390A's bandwidth and hope that Eldico crystal filter and applicable R-390A "mechanism a

philharmonic" (mechanical filter) center frequencies match (in contradiction of Murphy's Law).

You could bypass Eldico's crystal filter and change detector injection frequencies (crystal swap-a pain). If Eldico has enough gain, you could tap R-390A IF ahead of filters and feed to Eldico (involves mod to R-390A).

Subject: Re: [R-390] CV-591
Date: Fri, 17 Jan 2003 17:48:13 -0500

There's also another possibility. You know that the 455 kHz output of the RF deck comes as a balanced pair. Only one side of the balanced pair is used for the 2, 4, 8, and 16 kHz positions of the bandwidth switch. Thus you can take the other mini-BNC connector (P518) and feed that to the IF output jack. Then if you have that connection loaded by a high impedance input to the Eldico (if in fact the input impedance of the Eldico is high), then everything works fine. Depends on the sensitivity of the Eldico also. This technique works just fine with my Siemens D2007 Frequency Selective Voltmeter used in its high impedance mode and as a SSB IF strip and demodulator. Then you can compare the SSB performance of the R390A versus the Frequency Selective Voltmeter -- and the comparison isn't too bad. Yep, my FSV sounds better just like 30-year-later technology should, but not embarassingly better.

From: Roy Morgan <roy.morgan@nist.gov>

Subject: Re: [R-390] CV-591 Questions

.....is this the usual failure mode of a bathtub capacitor?

Usually they don't fail. hehe... leakage is more common than open I think, but whatever, yours failed open. You may be able to unsolder the case and fix an open connection.. though at that point a new cap inside is a good idea. (If you use an electrolytic, mark the polarity!) putting a new cap on the terminals of the old one is a fine solution though.

>The variable oscillator is VERY touchy to align. Any ideas?

Is the thing stable on crystal control (assuming you have the crystals installed)? Apply TINY amounts of De-Oxit or Pro Gold to the cap rotor wiping contacts. This thing is operating around 400 kc or so and should not be touchy in any way. Check ground lugs and capacitor mounting frame studs for corrosion. Also pay attention to shields in the same way. Replace all paper caps, if you have a flaky one in a bypass function, it may be wavering in value enough to affect the oscillator frequency. You may have a flaky trimmer cap. Be careful if you are tempted to force a ceramic trimmer that is stuck. I broke one and discovered that it is a temperature compensated one (N750 perhaps) and was not easy to replace. For our use the temp compensation may simply not be needed. Summing fixed and a variable cap is perfectly fine if you can't locate the right value.. These circuits should essentially stay tuned up forever once set. To save a bit of heat and unnecessary tube aging, removing the reactance tube as you did is a good idea.

The statement is incorrect. Any receiver with reasonable stability and a tunable BFO will receive LSB/USB. The R-390 and R-390A are in this category. The AGC system and/or the BFO injection level may not be optimum for quality reception but with judicious use of the RF gain control, and proper BFO tuning adjustment either sideband is received with reasonable quality - this applies to the R-39* family of receivers also.

Subject: Re: [R-390] SSB with the R-39* ...

> While I realize that the R-390A-R-390 will not receive LSB/USB...

Not true. ANY receiver with a BFO can receive SSB with proper use of the RF and AF gain controls, and tuning knob or BFO "pitch" controls, by the knowledgeable or experienced operator. I am presently using an Hallicrafters S-41G to receive SSB and it does a good job, although I had to add an "RF" gain (actually IF gain) control to reduce the gain a bit on strong signals to prevent overload. If the S-41G can copy SSB, the R-39* series sure as heck can. Perhaps you were jesting with the above statement? If so, I apologize as I am a little dense sometimes.

From: blw <ba.williams@charter.net>

Try tuning the radio per the A -10 manual. I don't know about the nonA manual, but I bet it is the same procedure.

1. Decide on your filter setting (4 kHz for this example)
2. Put the BFO selector to half of the filter setting (example- 2 kHz for USB)
3. Off tune your desired freq by what the BFO is set for (2 kHz up for USB or 2 kHz under for LSB)
4. Example- you want to tune to 6.955 USB with the 4 kHz filter. You would set the BFO to -2 kHz, and tune to 6.957 MHz. This should put you real close to the freq of 6.955. You probably won't need verification of your frequency as this is reliable. Learn your particular radio. My USB is a few kHz off, so I fudge that error in every time and I get dead on when I check frequencies. I can get accurate logs every time If you try it all of the variations you can with tuning/off tuning, BFO adjustments, etc, you will probably find the best audio and very accurate tuning using the -10 manual directions.

Subject: [R-390] SSB-Modified R-390A

I have a Collins-made R-390A S/N 756 from the very first contract (14214-PH-51). It was modified to add SSB capability. The BFO switch was changed from the "Off-On" to "LO-UP-AM-BFO" and the dial lock was removed and replaced with a "VFO Vernier" control.

The mod was very nicely done and works well, with screened lettering on the front panel, and there are no immediately obvious circuit additions from looking at the top of the chassis. I don't know exactly what type of mod was done, but it's certainly not a typical hack job normally associated with military radio conversions by amateurs. I have three questions: where can I find a list and descriptions of known SSB conversions for the '390A so I can identify the mod? Also, were there commercial conversions done by/for the government? This radio came from an estate which included equipment from a US Army experimental SSB station AN/GRC-108 XC-1, so perhaps this radio was modified for the Army and not by a ham. Finally, does a "professional" SSB conversion add to or lessen the radio's value? I guess it depends on the type of mod and who did it, but some thoughts along those lines would be appreciated.

Hi Jim and friends, very interesting. I agree with you that a MOD done (well done)

by factory or from Army Lab can add value to the receiver in the same way of some strange contracts (for example I have a 51J-4 manufactured from Collins for Yugoslavian Press Agency TANJUG silkscreened in yougoslavian language). Can you put on the web (or send by mail) a photo of your R-390A/URR for a better evaluation.

From: Rodney Bunt <rodney_bunt@yahoo.com>
Subject: [R-390] SSB-Modified R-390A - factory or not ?

I recently aquired a National HRO-Senior, it has 'factory' installed a minature tube for the Oscillator, and a Collins filter (2.1kHz)in place of the 1st IF can. It is so neatly done, soldering, components, mounting etc. if it wasn't factory it sure does look as good as. Very good on CW/SSB but too narrow for BC listening. Am looking to 'retro' the original IF can back in, anyone out there with a HRO IF can, T2 to be exact. Circuit is pretty simple, maybe a change over switch Collins Mechanical Filter / IF filter.

From: David Ross <ross@hypertools.com>
Subject: Re: [R-390] SSB-Modified R-390A

Does this describe the LSB-USB-AM-CW mod for the R-390A?

"Mounted on a small L-bracket chassis, it consisted of circuitry featuring a 6U8 tube with two crystals and a USB/LSB selector switch. The original BFO switch was removed and the new assembly installed in it's place. A short cable fit into an 8-pin connector added near the front of the IF deck for power and signal output. The front panel was refinished, repainted and silk screened with new lettering for the USB/LSB switch"

This is from the February 2003 issue of Electric Radio, page 32, article titled "Dick Walser Remembered". Dick is apparently the fellow who came up with this SSB mod. The article mentions Dick's company, Airborne Electronics and further states: "In all, Airborne remanufactured about one thousand R-390As. A large number of them were shipped to radio dealers in the (Los Angeles/North Hollywood) area. Not all of them went to the dealers.

Todd Shipyards purchased ten radios that were to be installed in five destroyer escorts being built in the 1970's, and in the 1980's a mysterious Japanese entrepreneur purchased twenty R-390A's for his well-heeled clients in Tokyo. Most of their rebuilt radios were shipped to well-known 3-letter Government agencies.

Some were shipped to countries in South America. R-390As that were under contract to Columbia Electronics received a new nameplate that reflected 'Columbia Electronics' as the manufacturer." Columbia Electronics does show up

as an R-390A manufacturer on an R-390A FAQ at:

Subject: [R-390] SSB Conversion Photos

Hi All: For those interested, I shot a couple of photos of the SSB conversion on my Collins R-390A. Here are the links:

<http://webusers.warwick.net/~u1016524/r390afront.JPG>
<http://webusers.warwick.net/~u1016524/r390assbadapt.JPG>

You can see on the front panel that the Mode switch positions are "LO-UP-AM-BFO" and the dial lock control is now a "VFO Vernier," which provides kind of a

fine tuning of the SSB signal, although in my opinion it's not really necessary, since SSB signals are easily tuned in with the main tuning knob.

The subchassis on the underside of the radio supports a 6U8 and associated circuitry. Near as I can tell from the photographs it looks identical to the rare factory SSB conversion described on R390-A.com, but since my radio is a Collins-made unit from the first contract in 1954, it's almost certainly a later addition. So there you have it.

Date: Wed, 23 Jul 2003 21:25:37 EDT
Subject: [R-390] R-390A SSB adapter

I've finished a new solid-state SSB adapter, and thought I'd share my results with the group. As some may remember, I built a product detector and AVC circuit which could be added to the R-390A without any mods. My first version used a variable BFO, so you could tune it to either side of the R-390A filter. This worked well- it was much smaller than a CV-591A, and was able to feed fast AVC to the receiver, making operation of the radio as if it had a built-in product detector. However it had a couple of drawbacks: First, the receiver needed to be recalibrated whenever you retuned the BFO to switch sidebands; second, my BFO circuit drifted some. So I built a new version around a 100 Kc crystal filter I picked up. Uses a 100 KC BFO, and switches sideband by switching the downconversion crystal oscillator. So its function is similar to the CV-591A. It's much more stable now, and no recal is needed when switching sidebands (or bypassing the unit for AM reception). However, it needs to work with the 4 KC bandwidth of the R-390A, in order to allow a passband of 2 KC with the 100 KC filter. The disadvantage is that the receiver AVC is open to all 4 KC of bandwidth, and so the gain can be affected by signals on the opposite sideband. Guess there is no perfect solution- I'm going to modify the old SSB adapter for crystal BFO, then I'll have to decide which one to use. I may hang the other on my SP-600.

From: "Veenstra, Lester" <lester.veenstra@lmco.com>
Subject: RE: [R-390] R-390A SSB adapter

Assuming you want to keep the use of the 2 KHz filter as a basis for the SSB adapter, I do not see a solution around the mechanical dial indication not giving you the SSB carrier freq as you shift from USB to LSB.

These thoughts occur:

(1) Assuming that you do have a true SSB filter(s) in the outboard unit, and that you derive the AGC signal past these filters, and assuming that your outboard product detector has sufficient gain (actually, input sensitivity) that your AGC feedback to the R-390 will keep its internal IF levels lower than are typical; With this assumption of low IF signal required, you reduce the chance that strong adjacent channel signals passed by a 4, 8 or even 16 kHz position will be a problem, with problem, in this case, meaning intermodulation products generated in the IF chain after the 455 mechanical filter and before the IF output to the external detector.

(2) Heresy? While you are building an external product detector, and want to use the internal 2 kHz filter, why not simply also tap the PTO output and build a pic based counter that can then have it's displayed value shifted for both USB/LSB and for front end offsets, just as you mechanically offset calibrate the PTO readout.

(3) Heresy and Blasphemy? O... Go ahead and simply build an outboard fixed LO frequency I and Q detector, A/D the I and Q channels and hand it to a simple DSP chip to do the heavy lifting.

From: DJED1@aol.com
Date: Thu, 24 Jul 2003 09:34:40 EDT
Subject: Re: [R-390] R-390A SSB adapter

Thanks for the comments, Lester. One original requirement I set out when I started the design was to avoid heresy- the SSB adapter had to connect only to existing connections on the rear of the radio. So it uses the IF output, the AVC terminals, and routes the audio back into the radio via the diode load terminals. This way the radio doesn't know its hooked up to a sand-state device. I've thought about some of the other items you mentioned, but I decided not to try and make the radio into something its not. Ed

Subject: [R-390] Re: Crystal calibrator issues on some bands

An update... I turned on the 390A to test Glenn's theory, and for some strange reason, the calibration points have somehow reappeared on those bands from which they were formerly missing. The only difference in operation was that I had my 390A plugged directly into the wall when I wasn't getting the calibration points on those bands, and had it plugged into a variac device when they came back (to go along with the recent variac discussion, I have so far been almost exclusively powering it up by variac with the function switch in the AGC position). I did seem to notice that those bands weren't getting any reception during the time that there were no calibration points, though I wasn't sure if there was supposed to be anything on at least some of them (usually, when listening this radio, I tend to stay below 10MC). If anything else comes up with this issue, I will report it.

Subject: [R-390] SSB on the 390 series

I have posted the method I was taught many years ago, and, If YOU have the patience to do it right, you will receive excellent SSB. Its all in getting the BFO at true "0", and understanding what SSB actually is, as far as pitch deviation is concerned, and what the ear is able to determine in change of loudness and pitch. These turn out to be minute indeed (Aprox 4 cents change can be detected by 90 % of people, for example, in pitch concerns...). I suspect many people really enjoy both building additional equipment, and having an operating system that doesn't require the care in prep. and use, that the BFO requires...However, I use the standard system for SSB, from ham, official, pirates, and unknown, and always am able to obtain full voice characteristics. Best Regards, John (JLAP)

Subject: Re: [R-390] Synchronous AM Detector Kit
Date: Thu, 24 Jul 2003 22:28:59 -0700

This technique is sometimes called "quasi-synchronous" detection. It works just fine as long as the carrier doesn't fade out. Using a PLL is generally preferred because it will "coast" over a momentary fade of the carrier.

The 2001 ARRL Handbook discusses this, starting on page 15.30. There is a circuit there that allows you to switch between synchronous and quasi-synchronous detection. It uses a chip that is normally used for FM reception, so it has a square-wave limiter output that can be used to drive the detector. I haven't built that particular circuit, so I don't know how well it works, but I enjoyed reading the article.

Subject: [R-390] SSB on the R-390 series

Had a couple req. for the method I have given, and exploited..Happy to send... however, it is given in basics in the Ops. Man. (TM 11-5820-357-10 ..for 390, and TM-11-5820-358-10, for the 390a I believe). My additions relate to further set-up, as I learned from my past ARMY friends..and a better understanding of the width of the sideband signal. I am really writing all this in regard to my past experience with the deviation + or - for the upper and lower sidebands. Mine is now BETTER. Where in the past I used + or - 1 to 1.5 hz, I now find since getting my receiver back this last time, that I just never vary from the figure of either +1 or -1. I believe because it is devoid of any probs in alignment and backlash at present...Does that seem reasonable? It would seem to be best in using a two hz filter width on my 390. The 390a should use a 4 for filter usually...Seemed to me in mil. practice that the 2 width was very hard on the hearing, due to the sharpness of the mech filter...Anyone else comment??? I would add, it is the same all the time, hot, after 3 hrs. or at 68 degrees after being off for several hours...WHAT A RADIO...

Had a note asking about the SP 600...I find it works fine on the 600; however it is simply not as accurate or effective for my man. read-out....Might be much better with an added ele. read-out. As I have said, effectiveness will vary from receiver to receiver..but it should work pretty well on any. The biggie is to be patient and learn the method. (Probably easier to get an SSB conv. if you are not interested in using the old method...)

- > at one end of the filter passband.

If using the 4 kHz filter in the R-390A, exact centering shouldn't be necessary. If using the 2 kHz filter, centering would be rather critical. How close can you set the Rycom? If a perfect 2 kHz filter in the rx, filter corners at 454.00 and 456.00, setting the Rycom to 453.70 for USB or 456.3 for LSB would give you an audio bandpass of 300 Hz to 2.3 kHz for . I assume the Rycom has xtal controlled BFO's of the correct freq for it's filters, which are probably about 3 kHz wide. Of course the R-390A filters won't be perfect. The 2 Khz filter is spec'ed at 2.1 kHz +/- 0.2 kHz at 25 deg C, +/- 0.3 over -55 to +85 deg C. A couple of 2 kHz filters I plotted recently

<<http://members.cts.com/king/j/jlkolb/site/curves/F455N201.PDF>>

<<http://members.cts.com/king/j/jlkolb/site/curves/F455N202.PDF>>
are a hair less than 2.0 kHz. 4 kHz filter at:

<<http://members.cts.com/king/j/jlkolb/site/curves/F455N40.PDF>>

At any rate, the perfect BFO freq for a 2 kHz filter will vary slight depending on the voice you're listening to, lower or higher pitched. Tune for what sounds most natural. You can also use the Rycom as an awkward passband tuning by offsetting it high or low from the perfect location, using the sholder of one filter to cut into the bandpass of the other filter and thus reducing the bandwidth below 2 kHz. John KK6IL <<http://members.cts.com/king/j/jlkolb>>

I started working on my CV-591 last winter. It required so many replacement resistors and capacitors in the RF circuits that I depleted the junk box. When the box of new parts arrived from Mouser there was no time to work on the unit. I just got it back on the bench. The first variable oscillator was making me crazy. It was veery touchy to adjust and it drifted constantly. I finished replacing all the

capacitors in the circuit and it was still drifting. The resistors checked out OK, so I tried some chill spray. The last culprit was the cathode/feedback resistor. On to the mixers!! I don't advocate wholesale replacement of parts, but if I was just starting this project I would remove the all vertically mounted "circuit" boards and replace all the components.

Subject: [R-390] Wally Chambers (K5OP) Audio Derived AGC

Quite a long time ago Wally told me about a very simple audio derived AGC mod for SSB consisting of one bridge rectifier and one 10K ohm resistor. I tried it, didn't think it did much of anything for the R-390A, so I put it in a box and was going to mail it back to Wally. But somehow it sat for years on my kitchen counter, and never got mailed. Eventually I moved it to one of my parts storage closets. A few months ago I noticed it and decided to try it again.

The AC leads of the bridge rectifier (a 1.5 amp 50 volt Rectron RB151, also Radio Shack 1151) are connected to the balanced line out terminals, the positive lead to the ground terminal, the negative lead to a 10K (later corrected to 1000 ohms... ed.) resistor lead, and the other resistor lead to the AGC jumper (either screw #3 or #4) on the rear panel terminal strip.

As I had done before, I turned the LINE GAIN knob to about 3. (Wally never told me what setting to use, and I never thought to ask.) And as before, I could tell that the mod was providing additional AGC voltage because of increased Carrier Level meter indications. And, yes, as before there was no noticeable improvement in the SSB quality. I still observed "pops" and "clicks" on some first syllables. For some reason I decided to increase the audio derived contribution by increasing the LINE GAIN setting. When I increased it to 4 and 5, SSB sounded a bit better. So I upped it to 6, and eventually 7. Above 7 it seems that the R-390A begins to be desensitized.

My opinion now of the K5OP audio derived mod is completely reversed. It is a great SSB mod when used in conjunction with my well-known AGC mod. It is also simple to do. I soldered terminal lugs (available from Radio Shack) to the AC and + leads of the bridge rectifier, and a short insulated wire from the "other 10K resistor lead to a terminal lug so that the mod can be implemented merely by unscrewing 4 screws on the terminal strips, sliding the lugs onto the screws, and tightening the screws. No soldering to the R-390A is necessary. Try it. You'll like it. It, together with my BFO vernier fine tuning mod, makes the R-390A a truly world class SSB receiver.

> knobs around here but not on an R-390A yet. Roy

No. My BFO vernier fine tuning mod is done with a voltage regulator, voltage variable diodes, and a 50K ohm pot (the pot added to the front panel in place of the DIAL LOCK mechanism). It was mentioned recently on the "qth" R390 reflector, and is described in detail in a file that can be downloaded from the FILES section of the YAHOO r390 reflector. Best regards, Dallas

> sounds interesting. Which AGC speed do you use, Slow?

I use whatever AGC speed band conditions (including QRM and QRN) dictate. But as you guessed, I normally use SLOW, and the audio derived AGC mod improves the SLOW AGC the most. I haven't looked at the audio derived mod yet with my scope, but I presume it substantially speeds up the SLOW attack time, which is very slow in an unmodified R-390A, about 10 milliseconds. To eliminate "pops" and "clicks" on initial syllables of SSB transmissions, I have found that attack times of about 3 milliseconds or less are needed. Remember, too, that the SLOW AGC of an unmodified R-390A uses a Miller effect AGC, which has an amazingly slow attack time of 200 milliseconds. I would be surprised if this audio derived AGC mod worked with SLOW AGC in an unmodified R-390A. Bur who knows? Maybe someone will try it and report back to us.

Subject: [R-390] Correction To "Chambers Audio Derived AGC Mod"

Well, I don't know how I botched it so badly. The 10K ohm resistor should be 1K ohms. And instead of being in the path to the AGC line, it is in one (either one) of the AC lines of the bridge rectifier to either one of the LINE OUT terminals.

From: Dan Merz <djmerz@3-cities.com>
Subject: Re: [R-390] Correction To "Chambers Audio Derived AGC Mod"

Hi, well, I wondered why it didn't work and was pursuing the cause. I found the mentioned RS rectifier in my junk box, still in the orig. package, probably 20 years old. But I got no effect with your described hookup - I'll try the corrected version shortly. But aside from that I found another quirk ?? in my 390a. I've never been happy with agc on the set - it has the two diode mod in the agc circuit. I began to wonder if the C551 cap was bad and tried the suggested test of switching between fast, med and slow setting to see if the indicated carrier level changed as an indication of leakage.. In doing this I noticed the quirk?? - when I switched from slow (which has B+ on one side of C551) to med or fast , the carrier meter pins to the upscale direction then drifts back to a level that is about 20 db higher. It stays at this level until I turn the rf gain down and back up, then it goes back to the lower level, about 20 db down from where it went went it drifted down from the meter pinned state. While all this is going on, I put a VTVM on the agc line and don't see this happening with the agc voltage. It didn't reflect this quirk, except it did go far upscale negatively when I switched from slow to med but returned to a level that was the same as before the switch. It there some kind of latching of the i.f. tube on the other side of the carrier meter, or is this likely a bad carrier meter. It seems to do it regardless of what the signal carrier strength is and shows no quirks when I move it up and down with the rf gain control. When I switch from fast to med to slow, in that order, the carrier level stays the same. Only when I switch back up to med or fast does the quirk occur, Dan.

Subject: [R-390] Attack Time Of K5OP Audio Derived AGC

This evening I measured the attack time of the K5OP audio derived AGC. It was about what I expected. With the LINE GAIN set at 7, and SLOW AGC, the attack time was about 1.5 milliseconds. A slight amount of "overshoot" (strictly speaking, undershoot) was observed. I can't hear it either in the lab, or when receiving actual SSB, so it is not worth getting excited about. A resistor (value to be determined) in the AGC line would probably fix it, and I may do that eventually. As the LINE GAIN is decreased (not recommended), the attack time increases. At LINE GAIN 3 the attack time is about 5 milliseconds, and as I said before, some pops and clicks are observed on initial syllables. I should add that the LINE GAIN pots in my R-390A's (and, in fact, all pots) have been replaced with new AP Type J pots (formerly Allen Bradley, but now Clarostat). If you have an R-390A with a well worn LINE GAIN pot, there is no telling how the K5OP mod will work in your R-390A.

Sorry about the mistakes. Your account of the CARRIER METER hanging rings a bell, but my memory just isn't what it used to be. Maybe it will come to me later. Unless you did the two diode mod yourself, my first guess would be that it was done wrong. When I get a "new" R-390A, the first thing I do is restore it to original. That has saved me a lot of grief in the past. If the problem remains after restoring it to original, you need to swap out the IF deck to determine if the problem is due to your IF deck or not.

The K5OP Audio Derived AGC probably won't work anyway for your R-390A because from your description it appears that your SLOW AGC is the original Miller effect circuit. The attack time of the original SLOW AGC is painfully slow, about 200 milliseconds according to my Hollow State Newsletter article. I'll stick my neck out on this one and say that the K5OP ADAGC just doesn't move enough electrons to charge a SLOW Miller circuit fast enough.

Subject: [R-390] Duuuhhh (K5OP Audio Derived AGC)

First, let me say how much I appreciate the stimulation questions I have been asked about the K5OP Audio Derived AGC mod. Sorry about the mistakes, and I hope you will be patient with any of my misunderstandings.

Anyway, I was asked, several times I think, if the K5OP mod would work with an unmodified R-390A. I said "probably not," thinking the question was about the SLOW AGC. But I forgot all about the MED and FAST. For all I know it will work just fine with them. I would do my old 2 diode AGC mod, though, (and remove R547, or unsolder one end of R547) because it is so simple to do, and it provides longer release times for FAST and MED (which is desirable).

Removal of R547 may cause the SLOW AGC to "hang" for a while and only slowly drop back to normal. I'm not sure on this, though. It has been too long since I studied the R-390A AGC variations. I have an unmodified IF deck that I will try with the K5OP Audio Derived AGC and report on that later.

Subject: Re: [R-390] Correction To "Chambers Audio Derived AGC Mod"

Dallas, I changed the K5OP audio agc gadget to the corrected config and it seems to help a bit on the reduction of distortion on initial attack. But that aspect wasn't too bad without it with the diode mod in place. I did the diode mod myself and I'm pretty confident that it's installed the way it should be. My story is a little more complicated than I stated since I'm using a 390 i.f. chassis in my 390a radio but I've convinced myself that this is not the cause of the quirk that I see. I'll

probably wait to see what characteristics you observe with your unmodified i.f. chassis as far as carrier meter hang goes since my 390a i.f. chassis also has the diode mod in it and I'd rather not undo the mod at this point and stick it in to see its characteristic. I would be interested in the observation of anyone else on absence or presence of this quirk of meter hang and whether or not the carrier meter is pinned in a set with or without the diode mod when switching from slow to med on agc. Dan.

Dan, You have two diodes (and I don't know what else you added, or what else you removed) in (to/from) your IF deck. Whatever results I get with my unmodified IF deck won't tell you anything about your IF deck possible problems. A lot of people have written about my AGC mods, and some of them have gotten it/them wrong. Maybe you were unlucky and stumbled across one of those versions. I would have to dig through my archives, but I believe there were two (possible three) "Lankford 2 diode AGC mods." Which one are you using? In these recent postings to the QTH R-390A reflector, when I referred to "my AGC mod" I meant my final one, the one which appeared in HSN #27. If you don't have that mod, then K5OP Audio Derived AGC mod probably won't do anything for you. Finally, you have only belatedly told me that your IF deck is not an R-390A IF deck, but a modifier R-390 (non-A) IF deck. It is likely that is why you are having those problems.

> quirk of meter hang <snip>

I've only seen this in a mechanically defective meter. You could disconnect it and play around with it on the bench to find out.

>and whether or not the carrier meter is pinned in a set with
> or without the diode mod when switching from slow to med on agc.

The meter pinning is a normal characteristic of stock R-390x's when switching from the SLOW to either of the other speeds. Theoretically my guess it the AGC-diode mod would behave the same way, but in reality the diode junctions may be breaking down to the large negative pulse generated when the AGC speed is switched. Might be a good idea to hook up a scope and take a look.

Date: Sat, 3 Apr 2004 13:04:25 -0600
Subject: [R-390] K5OP AGC Mod & Umodified IF Decks

I put an unmodified IF deck in my R-390A a little while ago and measured its attack times with a scope using the K5OP AGC mod. SLOW is awfully slow because of the Miller effect circuit it uses. The SLOW attack time was about 200 milliseconds with or without K5OP. Unacceptable for SSB. The MED attack time with K5OP was unmeasurable because it was an awful looking curve, not the exponential curve (or approximately exponential) that we need to assign an attack time to. It probably sounded bad to, but I didn't bother to listen. The FAST setting is unsuitable for SSB.

So there you have it. The K5OP isn't a stand alone AGC for unmodified IF decks. It is a helper which provides more electrons to give the optimal FAST attack needed for the SLOW AGC setting of my (last) AGC mod. When I have referred to my AGC mod, I meant the last one. I don't recall exactly how many AGC mods I published. Two or three. (And there is another one that I haven't published yet, but it is just a minor variation of the "last" one.) A lot of different people have written their versions of my AGC mods, some right, and some wrong. So you won't have to find out the hard way that you have a wrong one, I have uploaded my last AGC mod to the FILES section of the other R-390 reflector. <http://groups.yahoo.com/group/r-390/>

The access the file you have to register with Yahoo, and then you have to join the group. After you have joined the group, you can click on FILES in the side bar, then click on the Dallas folder, and then download the file (there are two others, the SSB filter file, and the BFO vernier fine tuning file). The AGC file is BIG, about 3 Megs. It takes a while to download. It also contains a simple mod to increase the BFO injection voltage. The BFO injection mod may negatively effect the AGC voltage. In that case you should re-neutralize the BFO. This is discussed somewhere on Chuck R.'s web site, I think, and probably elsewhere. I haven't checked this out myself because I never had any problems. The K5OP mod may work with one of my earlier (and simpler) "2 diode" mods. But I probably won't look into that immediately because I have other irons in the fire.

Subject: Re: [R-390] Correction To "Chambers Audio Derived AGC Mod"

Having applied this modification many years ago, I would say, it it without a doubt essential to the proper operation of an R-390A, either for AM broadcast/SWL listening or SSB listening. It (the two diode Lankford mod) eliminates the s-meter hang when switching to med agc from slow and improves listening in the am mode. Of course, It vastly improves the listening in ssb. I fully realize that many do not care to "modify" a R-390A, but that is their problem, not mine. Having known K5OP, and Dallas for many years, I can say without reserve, that those who haven't chosen to make these modifications are living in the dark ages.

Subject: Re: [R-390] Correction To "Chambers Audio Derived AGC Mod"

Dallas and others, thanks for your patience - hard to tell from the reprint of your article that I have whether it's HSN 27 or not - it's titled " R390A AGC/BFO Mods... By Dallas Lankford published June, 1990 if I'm reading their reprint format correctly - I obtained it from Nat. Radio Club R66 reprints quite awhile back, and I think the only thing I didn't do was take out the 220k resistor that one of the diodes bridges. I just added two diodes 1N4148's. In some 390 postings, this was referred to as Lankford HSN 23. As far as I can tell from other comments, the pinning of the meter is typical 390a or 390 action when switching from slow to med. The quirk of hanging at a higher level may be something else, which I'll pursue. I apologize for not mentioning the 390 i.f. chassis earlier but was really after information on what was normal for the 390a agc carrier meter when switching the slow/med/fast.

At this point, I'm thinking of trying another mod for agc published in Electric Radio Nov 2001. I corresponded about a year ago with Ron Deeter and he suggested a variation of this that he put into both a 390a and the 390 i.f./390a combination. These mods do away with the suppressor grid connections. For the most part, I dislike extensive mod's because I mostly like to appreciate the old sets for what they were. But I can always stick my original 390a i.f. back in for that purpose or for the next guy that gets it. Perhaps someone else has tried the Electric Radio mod. I'm not sure it'll be worth the effort beyond what the two diodes accomplish. My biggest desire is to accommodate ssb signals with big strength differences without turning the rf gain up and down constantly. I did take a look today through the archived FAQ's on the Lankford agc mod subject under 390 ssb mod's to refresh my memory on where I got the mod I made. All the info that originally lead me to make the diode mods was there, along with comments of others at the time on this reflector. There's a lot there on the subject. Thanks to all for the comments, Dan.

Subject: Re: [R-390] K5OP AGC Mod & Unmodified IF Decks

Dallas, I took a look at the posted agc mod you put on yahoo. It's the same article I have as a reprint from Nat. Radio, called out as R66, only cheaper this time since I think I paid them per page. It took about 25 min with a 56K modem. You did add a note about the difficulty of putting the complete mod. in an EAC chassis, located on the page of the schematic. I didn't put in any of the time constant capacitors mentioned in this article, just the diodes, so I guess my mod would count as an earlier type, as I left the grid/plate Miller effect circuit on the slow position in place. I recall that I did add the 47 pf BFO coupling cap. And to my embarrassment, I find you mentioned the pinning of the carrier meter when switching from slow to medium for an unmodified circuit, which goes away with removal of the Miller effect circuit. So if I did read this completely earlier, I forgot it. But it's good reading - maybe I'll remember it longer this time. best regards, Dan.

From: mikea <mikea@mikea.ath.cx>
Subject: Re: [R-390] CV-591 Audio

That's interesting. There are a couple of things I'd look at in this situation:

- o Scope or use a good RF voltmeter to measure the IF level from the R-390A; and
- o Use a good calibrated signal generator (HP 8640B, AN/URM25, etc.) to see what input to the CV-591 is needed to get good output level.

This should tell you which piece of gear to look at. After that, it's a matter of chasing signals from stage to stage until you find where the gain is lower than it should be, something is misaligned, etc. Good luck and happy hunting!

Last time I saw this: (1) C26 had shorted, which (2) burned R34 and C25.

I replaced these and all was well. Anything that causes extra current to flow through the 6AQ5 (V6) will stress R34. It is a 2W 560 ohm cathode resistor. Also, if C25 opens, it will reduce the audio gain quite a bit. I had already determined that there was plenty of signal getting to the audio stage.

Back a couple cycles ago I took a stock SSB CB and used it as a tunable IF for a 15 Meter Transverter Mobile Rig - worked great.

R390A SSB

The 6BE6 product detector mod is something I am working on right now with my R390A. I built the circuit using the Electric Radio article (ER-58) parts and am finding that it works pretty good. The injection is low and distortion occurs during high signal conditions however. Before this, I did the "competition grade" AGC mods that Ray N0DMS published in ER along with the stock diode detector mod. The 6BE6 product detector easily beats that (I kept using Rays AGC mod). Instead of fooling around, I intend to build the product detector stage up externally and characterize it "outside the box". I have collected a spare R390A BFO PTO coil assembly, tube socket, IF can etc.. and am mounting them an a small BUD box. I also collected a variety of pentagrid converter candidates which may outperform the 6BE6.

From: Bob Camp <ham@cq.nu>
Subject: Re: [R-390] R-390A IF and AGC

Oddly enough there are two ways to do a tube diode and the equivalent in solid state. A triode grid will work as a diode and it often does a better job than a straight vacuum tube diode. The main advantage is that it's "forward voltage" is a bit lower so it makes a more efficient detector. The same thing turns out to be true with the

base emitter junction of a transistor. It makes a lower leakage diode than a normal silicon diode. You can also get low barrier hot carrier diodes in solid state.

An AM detector has a bunch of characteristics. The first is the ratio of RF power in versus the audio power out. Solid state diodes are lower barrier but also lower impedance. That makes things a little hard to compare directly. The next characteristic is signal to noise. Here lower impedance is generally better. I suspect the combination comes out in favor of the solid state diode. Assuming the IF strip has enough gain and that signal to noise is set before the detector neither of these things probably are a big deal in a properly designed real radio.

If you swap parts back and forth in a radio without redesigning it I would bet the difference might be more noticeable.

What probably is important is the linearity of the diode. Most grid based tube detectors have a noticeable non-linear component to them. The solid state diode may be a bit more linear but it's a toss up.. Neither one of them is as linear as some other ways to do the rf to AM conversion process. What is for sure is that each will have a different distortion characteristic. Most people like the tube distortion better than the solid state distortion

No matter how you look at it the fast attack / slow decay that the common AGC mods add to the radio work better than the stock AGC

Subject: [R-390] Baker and Williams

Someone told me that they obtained a SSB outboard unit for the R390A from Baker And Williams. I went to B&W's web page and couldn't find anything there concerning this? The fella who mentioned the unit has a problem answering email, so I was wondering if anyone out there on this reflector has any information about this unit?

From: Roy Morgan <roy.morgan@nist.gov>
Subject: Re: [R-390] Baker and Williams

The B&W unit is the "Model 370 Single Sideband Receiving Adapter." It operates on the frequency conversion principle, with its low IF frequency at 17 to 20 Kc. Upper or lower sideband is selected by changing the mixing frequency. A filter at 17 Kc selects the desired band of frequencies. There is a 17 Kc injection oscillator to re-inject the BFO signal for SSB, CW, or enhanced am operation. The thing contains an audio amplifier (6V6) and speaker. These units seem quite hard to find. I have one, one other fellow I know of has one also. I also have an original manual, and will be happy to provide copies of it to anyone who needs one (it is not on the BAMA site - When I get the time, I'll scan it and send it in for all to have.) Other sideband adapters that can be used with the R-390A or other radios with 455 kc IF frequencies include:

Hammarlund HC-10: quite rare and expensive
Hammarlund SPC-110 rack mount equivalent: even more rare and expensive

Military CV-591 (aka MSR-4) made by TMC sideband adapter
Any modern rice box that will receive SSB and tune to 455 Kc.

Subject: [R-390] Re: B and W SSB Adaptor

I sold those when I was a B and W dealer and later a lot of used ones came through the doors when fully SSB receivers came along. There were several similar units popular in early 60s and prior. B and W was a no nonsense unit that worked very well and was a companion to the 5100B transmitter and 51SB SSB Adaptor. Add one to a 75A3 or similar and you had a great receiver. Lakeshore, Eldico, and Central Electronics made various models with various results. Most of the Central units were in kit form and I had to rework so many I quite taking them in trade as did my friend Bob Henry.

The jewel that people wanted but was rather expensive was the Hammarlund HC-10 and SPC10....SPC was rack mounted. It was literally the whole front end, IF strip and all from a HQ-170/180 with the excellent SSB system, stagger tuned IFs, and other features. Being a Hammarlund dealer I sold them as fast as I could get them.....many went on NC300s and 303s. I put one on an AR-88 and it is still there. Also used others on a my R388 and R390A and a couple of commercial receivers.

But when all is said and done the TMC strip rack panel adaptors were a terrific bargain when several surplus stores were selling them for \$50. I bought four and three had off freq crystals (they had your choice of variable tuning or crystal controlled USB/LSB. I bought a handful of crystals from International and made them do what they were supposed to do. Still have one and like it for it's simplicity. A natural with the R390A.

Sooo it is all in what you are looking for in additional features beyond just adapting to SSB.

There were lesser units on the amateur market but the didn't last long. One great thing about the B and W was a front mounted speaker of high quality.... But then all their gear was great!

Subject: Re: [R-390] Baker and Williams

Why not just do the Lankford agc and product detector modification? I have that on my 51J-4 and it works spectacularly! The agc mod takes care of the crappy audio when listening to fading sw broadcasters and the product detector is superb. No need to vary the bfo, as it is a true product detector, center the bfo in the passband and listen away to USB or LSB with equal ease! The articles were in HSN 26 and HSN 28.

From: Bob Camp <ham@cq.nu>
Subject: Re: [R-390] R-390 sideband adapter

Probably the biggest single thing that needs to be done for any SSB adapter to work well is the (dare I bring it up ...) Dallas Lankford AGC mod. Without a better attack / decay ratio on the AGC SSB will be a problem. To work properly the AGC needs to be applied to the full receive chain and not just the IF. If you don't mod the radio internally then you need to derive the AGC externally and feed it back into the radio. Another interesting challenge is that the output level from the R-390 is a bit lower than the level that comes out of most modern radios. That makes matching up the radio with just any adapter a little tough. Do you really think this SSB stuff will be around long enough to make it worth setting up for?

Date: Mon, 17 Jan 2005 16:48:12 -0500
From: Gord Hayward <ghayward@uoguelph.ca>
Subject: [R-390] R390 Sideband Adapter

I added an outboard dual product detector with the crystal BFO fed to the two in quadrature (90 degrees out) and listen to the two in stereo. It does nothing to the SSB signal but seems to make the noise three dimensional and almost pleasant. Later I'll extend this into an ISB detector but I haven't got the time right now. So far the AGC hasn't been an issue.

From: DJED1@aol.com
Subject: Re: [R-390] R-390 sideband adapter

I certainly agree. In the 70s I bought several CV-591s (\$35 each from DOD-wish I had kept them as an investment), which helped, but they didn't have a convenient speaker output, and took up a lot of space on the desk. I tried my own version of Dallas' AVC mod, and the audio driven version. However, none were really satisfactory without a product detector, and so I built the solid-state product detector and external fast attack AVC. The AVC voltage is derived from the IF output, and only requires a couple of transistors and diodes. The AVC characteristic is not as flat as my R4C, but the R390 was never specified to have a real flat AVC characteristic. I can listen to widely different signal strengths now

without any distortion. I've been pretty happy with it, although my BFO is not as stable as the internal BFO. I picked up a couple of BFO crystals which I will add to the unit one of these days.

Subject: Re: [R-390] Product detector kits

Jan's detector is a variant of a circuit I offered to the board several years ago. I have one problem with his circuit in how it differs from mine. As best I can tell from his published notes, he has included the product detector, but not the auxiliary fast attack AVC which I included in my circuit. He says in his writeup that you need to reduce the RF gain for strong signals, while my AVC allows full gain on signals up to 80-100 dB. His detector may work well if you have modified the radio's AVC with the Lankford modification.

From: Bob Camp <ham@cq.nu>
Subject: Re: [R-390] Product detector kits

AGC is a pretty darn important item. Audio derived AGC is about the only way to go with SSB. One way or another the radio has to have AGC to make a product detector work well for band cruising. Matching the AGC to the detector is an important part of the design. Manual gain control works, but it's a pain as you tune through a crowded band. That said just about any kind of product detector is going to work better than the BFO in a stock R-390. A lot of this comes down to outboard boxes versus internal modifications. Maybe Jan will offer a product with the full circuit in it ...

From: Bob Camp <ham@cq.nu>
Subject: Re: [R-390] Lankford 2 diode agc mod problem

You are dealing with fairly high voltages in the circuit. Depending on the diodes you use this may be an issue. It's probably easier to just use diodes rated high enough to withstand the transient than to monkey with more parts in the radio.

Subject: Re: [R-390] Re IF Deck Product Detector Add On

There have been discussions on this list for years about adding a product detector to an R390A. My feeling is why bother with it. The R390 series are all fine radios but for whatever reason they didn't build them with product detectors. As you know I have the Eldico Electronics SBA-1 SSB adapter this unit vastly improves the side band performance of My 1967 EAC R390A, it adds a notch filter and a good 2 watt audio amp. If you want to improve the side band performance of the R390 get one of the many side band adapters that were made instead of modifying the receiver. For SSB reception There are so many good receivers and transceivers out there with product detectors as part of their original design I can't see adding one to the R390

>... probably doesn't work. Bid is now at \$300 and will probably sell higher.

>Looks like a hint of blue paint on the face. Doesn't look like a good buy to me.

Nope, it does not, But.. most of them need their caps replaced big time, and often have bad relay contacts that need attention. Nothing impossible, but any CV-591 that works right off the bat has had SOME attention lately.

>...several different Single Sideband Converters were used with the

>R-390A.... which one works the best and what is the going price for one in

>working condition?

They all work more or less well, but others have had more experience with a variety of them and can tell you more. I've not followed prices lately but here are some guesses on the ones we hear most about:

- CV-591, complete and working or restorable: \$300 and up

- HC-10 Hammarlund separate box: \$400 and up

- The SPC-10 (rack mount - meant for use with the SP-600): \$600 and up

That's all pretty discouraging, BUT, if you have a rice box that covers 455 kc, use a 60 db pad and run the IF output from your R-390 into the receiver. Folks who've done this report good results. All you need is a bit of wire and a couple of resistors.

Subject: RE: [R-390] Tell me about Single Sideband Converters

This should be an interesting thread. In all of the years I have been on this list I do not remember an in depth discussion of these hollowstate Side band adapters. I only have experience with my Eldico SBA-1. I would like to learn about the other such units manufactured. The CV-591A/URR is a Collins made unit. As you know most anything Collins puts a premium on the price working or not. The only unit I

can comment on is the Eldico Electronics SBA-1 adapter I have. The bottom line is works great it makes the tuning of SSB on an R390A just like any modern rig. I am sure the engineering on the Collins adapter might be better; I have not been able to do an A-B comparison. Being able to tune a side band phone round table without having to ride herd of the RF gain is really nice. The SBA-1 has a 4 watt audio amp, a noise blanker, which isn't as good as the one on the R390A which really is no surprise, a notch filter, and a AVC setting fast/slow, as well as the usual controls for audio volume, mode, IF gain, standby/receive. On the back panel there are connections for AVC, muting, speaker connections For 4 and 600 ohms, and IF signal inputs for hi and low impedance.

>From a boatanchor pilot mind set I like these units because they where a contemporary hollowstate solution to the SSB deficiencies of the R390A. As I have reported the when you place the SBA-1 on top of the R390A the controls on the SBA-1 match the flow of the controls on radio.

From: "Bill Hawkins" <bill@iaxs.net>
Subject: RE: [R-390] Tell me about Single Sideband Converters

The CV-157 is the best? Well, that depends on your tolerance for heavy equipment, about 110 pounds. I have one from a guy who shipped it in a paper towel carton packed with peanuts, stuffed with random tubes. Cost me \$300, but I was young and foolish. Guy seemed to have stopped taking his meds when I told him that one corner of the works in a drawer looked like someone had stepped on them. Completely unreasonable. So here I am with a complete CV-157 with a rebuild tag and mostly the wrong tubes. I have lost my fascination with the servo controlled carrier centering device, but it's all there. I started to unhook wires to the drawer in order to remove it and fix the squashed 100 KC amplifier. I did isolate the filters and check them with a scope and HP 200CD, all looked good, made by Orion. Yes, there's a copy of the manual. Anybody want to make an offer over \$150 plus shipping? Hate to see a rare piece of gear languishing in a corner of the warehouse. Preference to pickup in Bloomington, MN 55438 but can ship it.

From: "bernie nicholson" <vk2abn@bigpond.net.au>
Subject: Re: [R-390] ssb converters

Ok Todd Most of the CV 157 s that I have repaired for people have lots of faults due I think mainly to the heat build up causing component deterioration, also they were designed for SSB with pilot carrier so that the discriminator can lock on. In the fifties, in the days before frequency synthesis, this was necessary to stay on frequency for SSB as we know it today. There is a lot of redundant electronics in the CV157, I have a similar unit designed for the Racal RA17 and it only has about 10 tubes, is very reliable, takes 4 inches of rack space, and only weighs 25

pounds. So you can see what I mean about over engineering. The TMC device is an elegant little gadget and works really well and has a low component count making it VERY reliable, and you can tune about in passband of what ever mechanical filter you have selected, I have never owned one but I have repaired them and always been impressed with their simplicity operation, Regards to every one.

From: John Kolb <jlkolb@jlkolb.cts.com>
Subject: Re: [R-390] Tell me about Single Sideband Converters

The CV-157 wasn't really intended as a voice SSB converter - it was intended for applications where a pilot carrier was transmitted. By phase locking to the pilot, the transmitted audio frequencies were recovered within a couple of hertz of error. We had a couple aboard the USS Providence in the Navy for use in receiving multiplex RTTY transmissions. These had, as I recall, an 85 hZ shift, so the receiver had to be pretty exact. I believe a set of two CV-157 and two R-390s in a single rack was known as a FRR-39. The production numbers for these would have been very low. No the other hand, many of the R-390's I saw aboard ship (early/mid 60's) were in a cabinet along with TWO CV-591's.

Date: Fri, 01 Jul 2005 09:31:40 -0400
From: Sheldon Daitch <sdaitch@ibb.gov>
Subject: Re: [R-390] Tell me about Single Sideband Converters

I might disagree slightly about the CV-157 not being designed as a voice SSB converter, in fact, I'd say that was probably one of its design parameters. John is correct in regards to the pilot carrier operation, but I'd further say that if the CV-157 were phase locked to the pilot carrier, there would be little or no frequency error. One of the systems applications for the CV-157 was four channel ISB operation, 16 kHz bandwidth, with two 4 kHz audio channels on each sideband. And usually one of the four 4 kHz audio channels was devoted to a 16 channel AFSK tone pack. I suspect the tone pack was always one of the "inner" audio channels to eliminate a frequency translation on transmit and receive.

If this isn't readily clear, let me try to explain. The upper sideband, for instance, would be modulated with one voice channel roughly 4 kHz wide, that was not translated in frequency. The second voice channel, also roughly 4 kHz wide, was translated upwards by 4 kHz, so that in the side band, it occupied the sideband bandwidth of 4 to 8 kHz. The same for the lower side band. Since the AFSK TTY frequencies are critical, the AFSK channel would be on the lower portion of the sideband, to eliminate that 4 kHz shift. I don't recall what units were typically used for the 4 kHz shift, maybe it was a TD-97/98 combination, but the brain cells aren't working too well as I type this. Whatever the nomenclature was, they weren't normally part of the transmitter or receiver set. When VOA ran the ISB/SSB feeders, we ran a pilot carrier, about 20 dB down from the PEP power rating of the transmitter, and our RCA SSB-3A receivers were capable of ISB reception, and

used a motorized AFC system very similar to the CV-157 AFC loop.

the AGC amp didn't work due to my drawing errors!

Did that back in the year 2000. In any case, I have already corrected my schematic
print, and hope to scan it soon and update the Web posting. I also plan on
crediting you with sharp eyes and much patience, if that's okay with you.

My actual circuit certainly does have a gain-boosting source bypass cap across the
1-kohm source resistor in the FET pre-amp stage. However, as I indicated in my
previous note, the rule of thumb I follow is that the reactance of the capacitor
should be about a tenth of the source resistor's value (or cathode resistor in the
case of a tube, or the emitter resistor in the case of a common-emitter amplifier
using a bipolar transistor). The actual cap in my circuit is a 0.01-uF Mylar type.
Using the formula for reactance $X_c = 1/2\pi f C$ yields a reactance of 34.9-ohms.

While that's not exactly 1/10th, it's close enough for government work, using
standard parts from the junkbox. Using a 0.1-uF cap, as you note, would drop the
reactance at 456-kHz to 3.49-ohms, which seems far too low. The approximate 35-
ohm value is close. A 0.001 would provide 349-ohms (likely too high). As for the
polarity error on the follower stage, I can only wonder why I didn't spot that as I
drew and scanned the diagram. That PNP stage could have just as easily been
implemented with an NPN device, and then I probably wouldn't have made that
error.

My cap is indeed inserted with the plus end at the highest point of potential, high
(obviously, now) is the Vcc line. Its purpose is to ensure that the emitter is close to
ground impedance (low). It probably ideally should be connected from the emitter

of the PNP follower stage to ground, and then the polarity would be okay as shown, if it were drawn that way. But that's not the way I hooked it up. In any case, you want the PNP stage's emitter to have no 456-kHz energy there, thus the bypass's function. You can poke your scope probe there to verify that.

Please feel free to punt this e-mail over to Ed if you wish to. My sincere apology for your inconvenience! Regards, AI2Q, Alex .-.-.

Subject: [R-390] Product detector for 390

Hi, a short report on my success constructing the product detector designed by Ed Newman/ modified with xtal control and posted by AI2Q, with reference noted earlier on this list. I deviated somewhat from the posted diagram and Ed's design by using a Hartley oscillator with a National NC-100 bfo coil but more or less the same configuration otherwise. The detector requires no mod's to the 390 (or 390a) and is an external box connecting to the diode load terminals, the i.f. output and the agc terminals on the back of the 390. With the oscillator I used, one of the buffer stages following the oscillator was unnecessary and a 300 mv signal to the 1496 IC pd was accomplished with an MPF-102 oscillator followed by the MPF-102 stage to the product detector.

The product detector improved the clarity of ssb signals and more importantly the design provides agc that works nicely with the rf gain control turned all the way up, or slightly reduced. The agc is a big improvement over what I accomplished with the simple two diode addition. The 390 noise limiter does not operate in the product detector mode. However, the unit has a single switch to revert to normal 390 operation with the 390 diode detector/noise limiter if desired. I hardly use the noise limiter so I haven't missed it yet.

I'll probably build a second one and use an R-392 bfo coil for the oscillator and make it compact enough to fit below the 390a in its cabinet. A nice unit, thanks to Ed and Alex for revealing their handiwork to the list, best regards, Dan.

Subject: Re: [R-390] SSB adapter for R-390A

>Would a 455 KHZ Central Electronics Sideband Slicer Model B, do a good as
>a product detector on a R-390A?

Yes, but you may have to reduce the IF signal going into the Slicer.. the signal from the IF OUT of the R-390A may overload the Slicer. Especially if your slicer has the little amplifier module on it.

From: "Ziegenbein, Randy" <rziegenbein@volcanotherapeutics.com>
Subject: [R-390] R-390 rf gain

I'm new to the R-390A world and have a couple of questions.

My 390A is a Collins first production run and has a mod so it supposedly receives SSB better by a couple of 4148 diodes in the agc ckt (one in parallel with R-547, grid of the AGC time constant, one in parallel with R546, grid and plate of the AGC rectifier ckt, and finally a 47 pf in parallel with C535, which is the coupling cap between the BFO and the Detector. Is this a good mod? Next, the RF gain control seems to only be effective the last 1/4 turn clockwise (man or agc modes). Is this normal or do you think the pot is bad or some other problem in the rf gain control circuit? Or is it a result of the AGC mods above?

Date: Tue, 6 Sep 2005 14:25:05 -0700
From: "Dan Merz" <djmerz@3-cities.com>
Subject: RE: [R-390] R-390 rf gain

Randy, this mod is well known to be an easy "fix" to improve fast attack on ssb signals and does improve the set (so-called "Lankford mod"). The connections you describe are what I have in my set. It doesn't eliminate the need to ride the rf gain control to accommodate weak and strong ssb signals, which is somewhat inherent with the relatively weak bfo injection relative to strong signals. I only conquered this situation by attaching an external product detector with its own agc circuit. There are other fixes, involving on-board product detectors etc. and another somewhat more elaborate mod similar to the one you describe.

I'm not sure what you mean by "effective"... Does it affect the meter response on am signals over the whole range or just for the last 1/4 rotation? I think normal is for the meter indication to drop over the whole range of rf control rotation for a strong am station, such as a strong broadcast station. But on weaker stations, the effect of the first part of the rotation from lowest gain may not be apparent.

Subject: [R-390] R-390 Langford SSB Mod

Some of you maybe considering or have the Langford SSB modification in your R-390's and be interested in my experience installing it in my non-A R-390.

I'm very impressed with this simple and easy to do modification which is easily reversible if you are not happy with its performance. On very strong SSB signals it does have a very slight tendency for overload but is a great modification if you plan to mostly use your R-390 for AM reception but occasionally to monitor SSB. If you experience any overload just back off the RF gain a bit. If you are planning to mostly work SSB than a full blown product detector maybe a little better, but not much. Also if you are using a non-A R-390 like mine and the SSB station your

receiving has poor opposite side band or carrier suppression there will be a slight distortion due to the beating effect due to the less steep shape factor of the LC filters compared to the mechanical filters of the A model.

I did run into one little bug that degraded the audio of AM signals but only with fast attack AGC. This was caused by some audio getting onto the AGC line due to the decreased impedance between the AVC rectifier tube and the AGC circuit by adding the diodes across the 180K and 220K resistors. It was most noticeable when listening to music by a reverb type sound on low pitched instruments such as drums.

I easily solved by adding a 0.5uf cap of at least 25 volt between pins 1 and 2 of the AVC switch, S104 on a non-A or pins 9 and 10 of S107 on a A model. This completely by passes audio off the AVC line and only slightly slows down the fast AVC, which I think is too fast to begin with. I put the cap on the AVC switch to not affect the time constants of the medium or slow AVC which I didn't want any slower. After adding the cap the fidelity of AM is excellent in all AVC modes. This was the only change to the original Langford modification I found necessary.

For those of you not familiar with this simple and effective modification let me summarize it here. Carefully remove the IF module after unplugging the power and BNC signal connectors, loosening the two clamps and uncoupling the band width and BFO shafts, then loosening the three green screws securing the module to the chassis. Add a 1N4148 diode across each of the 180K and 220K resistors between the AGC rectifier tubes anode and the AGC circuit, R556 and R557 on a non-A or R546 and 547 on a A model. Install the diodes so their cathodes are toward the plate of the AGC rectifier tube. This will convert the AGC circuit to fast attack slow decay.

Add a 47pf, at least 300 volt, dipped mica cap across the 10pf output cap for the BFO that is connected to the BFO tubes plate, C536 on a non-A or C535 on a A model. This increased value of 57pf for the coupling cap will increase the BFO injection to the audio detector.

After checking your work reinstall the IF module and test the radio on AM and SSB stations. Offset the BFO +1 to 2kc for LSB in the 2 or 4kc selectivity positions. For USB offset the BFO -1 or 2kc. Adjust the BFO and main tuning dial for best audio sound. Then if you also notice the slight distortion of AM signals in the fast AGC mode, add a cap to the AGC switch pins as described above. Physically installing the cap was the hardest part of the modification on my R-390 because of the BFO bellows covering the area of the cap but using a small soldering tool hemostats and some patience was possible. Installing the diodes was easy on my R-390 because the two resistor are easy to get to on TB502 located on the back wall of the IF module.

Hope my experience is helpful,

Subject: [R-390] Y2K Manual

<snip> I do have a couple of questions on the 591A.....

1. For some bizzare reason, the USB and LSB positions appear to be reversed. I had to switch xtals to get it to detect the SSB signals as indicated on the front panel. According to the 591A Manual, the xtals were in the correct position, but I had to switch them, to get it to function correctly. Could the 390A be THAT far out of alignment? The audio sounds great with the xtal swap, but..... somethin' ain't right.

2. Never having used this combo before, I was VERY disappointed with the audio output of the 591A. I have to use an outboard audio amp to get decent volume. Tubes are good, been recapped, voltages normal etc. Any thoughts? I do have a junker 591A I picked up because the filter choke in mine was fried. I don't mind using the outboard amp. In the same rack, is a 51J-3 with a solid state (Ron Hankins?) SSB adapter. Of course, this one absolutely needs an outboard amp. I just thought the 591 with it's 6AQ5 audio tube should provide as much volume as my other boatanchors which use the same tube..... thank you in advance!!

Subject: Re: [R-390] Y2K Manual and CV-591

>I intend to start 'going through' my working and very mint '67 EAC.

Good for you. I also have a nice EAC-67 here. Mine is kaput, but I'll get it working nicely when I get to it.

>...if anyone has an 'erratta' list for the Manual.....

First, make sure you have the "Release 2" version. It is here: <http://www.r-390a.net/Y2K-R2/> On that page is a set of errata for the Release 1, but as far as I know they have all been accounted for in Release 2. There may well have been some errors detected in Release 2, but I don't know of a list of them.

> ... the 591A.....1. For some bizzare reason, the USB and LSB positions appear to be reversed.

This is an oddity but not unexpected. The thing can be used with receivers that either reverse the sideband sense or do not reverse it. This comes from the local oscillator being above or below the mixer input frequency. The manual for the 591 talks about this situation. You may have discovered that the way to "switch" the thing is to reverse the bulb covers on the two indicator lamps!

>I had to switch xtals to get it to detect the SSB signals as indicated on
>the front panel. According to the 591A Manual, the xtals were in the correct
>position, but I had to switch them, to get it to function correctly.

Good if it works for you, fine. The whole thing is a bit of a puzzle for me, at least, even though you'd think it was easy to understand and keep straight.

>Could the 390A be THAT far out of alignment? The audio sounds great with >the
>xtal swap, but.....somethin' ain't right.

I suggest you get a signal generator and do a little experimenting. Think slowly. Turn the knob slowly. Get clear in your head where the signal generator is with respect to the passband and the local oscillator(s) For example: if you tune your signal generator from ABOVE the frequency the receiver is tuned to, and the first audio you hear it HIGH frequency (like 2-3 kc) and decreasing, then your signal generator signal is above the tuned frequency and you are in the upper sideband.

> 2. Never having used this combo before, I was VERY disappointed with the
>audio output of the 591A.

I think you are not the only one. I suggest you make VERY sure that the coupling caps in the 591 are replaced: especially the ones in the audio section. ALL, repeat ALL EACH AND EVERY ONE of the coupling/bypass caps in my CV-591 are leaky. In the audio section, this causes excessive plate current in the audio output tube. In particular, C20 and C24, both 0.01 uF may be leaky. C24 especially may be leaking and driving the 6AQ5 plate current way up, causing lots of distortion and weak audio. Test also C25 and R24, cathode bypass and dropping resistor for the 6AQ5. Measure the cathode voltage to be sure nothing is amiss. replace all three of these caps, unless C25 is a paper oil (2 uF) and is not leaky or defunct. Try feeding audio into the thing at the appropriate place to see if the whole audio section is working. Modulated 455 kc from the signal generator will tell you a lot, too.

> I have to use an outboard audio amp to get decent volume.

Notice that the audio output section is configurable for "low level" output (150 mW) or "high level" (2 W) and also can drive 8 ohms or 600 ohms. Dope that out in your mind and get it set up straight. The switch that does this is on the chassis near the rear terminal strip, I think.

> Tubes are good, been recapped, voltages normal etc. Any thoughts? I do
>have a junker 591A I picked up because the filter choke in mine was fried.

Of course you don't need the junker now, so send it to me.. thanks. (heheh)

> I don't mind using the outboard amp. In the same rack, is a 51J-3 with a

>solid state (Ron Hankins?) SSB adapter. Of course, this one absolutely
>needs an outboard amp.

You mean the 51J-3 absolutely needs an outboard amp, or the SSB adapter
needs it? I have an R-388 that I have not yet got running, so that's why I ask.

> I just thought the 591 with it's 6AQ5 audio tube should provide as much
> volume as my other boatanchors which use the same tube.....

That makes sense, but it may simply be lame by design. How does it sound with
good earphones?? Roy

Subject: [R-390] 390A SSB "Stock Mod" info search

This may or may not be fodder for some of the latest info updates or what have
you, but I've not seen it online, not on Pearls.... There seem to be several 390A's
around with SSB mods, some are said to have come from mil surplus in that
condition. Over the years folks have posted pics here and there, and there was a
good writeup on a book by an Italian fellow that went over that mod. Not sure if that
book is still in print, etc. (if it is, I'm broke, etc.)

Many of us have seen the product detector mod that's in Cap't Lee's "Mars" mod
series, but this is a different sort of thing, for those that aren't sure what I'm talking
about. This lashup has a small box that mounted just behind the headphone jack,
apparently there were assorted different versions, some may indeed have
followed the mars mod. There was at least one modded radio discussed in the
distant past on this list (ten years or so ago, more?) that supposedly "came that
way" though I can't find the messages I'm looking for in the archives about it. May
have been discussed on Boatanchors.

If nothing else, does anyone still have a copy of the book I'm thinking of?

From: "Brad Huff" <huffb@avalon.net>
Subject: [R-390] Single Sideband reception with the R-390/R-390A

I would like to thank all of the people that responded to my signal generator question a few days ago. I received responses within minutes of my posting. Unbelievable! That is what makes this group so great. I would now like to open a discussion about single side band reception with the R-390/R-390A series receivers. For the purpose of this discussion let us assume that the radio has been altered such that the AGC has been modified for proper SSB reception. I have had experience with: 1) the radio with no external adaptors and increased BFO injection.

- 2) a CV-591A SSB adaptor.
- 3) a Hammarlund HC-10.
- 4) a Central Electronics Sideband Slicer.
- 5) a Sherwood Engineering SE-3
- 6) a PD-1.

I have not had any experience with the Capt. Lee onboard product detector mod or a couple of the home brew units that are out there. I have schematics and have ordered parts for one of the home brew units I just have not had the time to build it yet so I can not comment on these. The adaptors that I have mentioned are not necessarily in any particular order as far as favorites, I just listed them as I thought of them. They all work. Some work better than others, and some folks can probably detect differences in the various units better than my tin ear. That is where you guys come in. I am curious as to your experiences and what you feel are the best units. Maybe we could rank the units that I have mentioned. Some units require external hardware to operate, that is, external amplifiers etc.. Some units will allow the audio to be fed back in to the receiver at the rear of the unit. Much has been written about the quality of the stock audio but I have found that the audio is quite acceptable if the audio deck is altered using Mike Murphy's suggestions. Any thoughts? Please respond to the entire group, it will be interesting to see what everyone's experiences are. -Brad

From: "Dan Merz" <mdmerz@verizon.net>
Subject: RE: [R-390] Single Sideband reception with the R-390/R-390A

Hi, I was pretty happy with the Lankford mod using a couple of diodes on my 390a but this didn't handle range of signal strengths without riding the RF gain control. I built an outboard product detector ala Ed Newman WB2LHI/Alex AI2Q that uses a LM1496. I've been happy with this and I never have to touch the RF gain control, which remains at the highest gain position. The unit has built-in AGC and is attached with no mods to the set, with 4 connections (i.f., diode load, audio, agc) at the back of the 390a or 390. My version was built using some old National NC 100 coils for the BFO and tuned output circuit for the BFO. It is set to the appropriate sideband with a knob on the front of the coil can and exhibits no drift of the setting. I can easily switch the unit out and compare original performance without it. The biggest advantage is the improved AGC, with some slight improvement in signal quality, compared to the original detection

scheme in the 390. I use it all the time on my 390. I was dedicated to the idea of an outboard unit without modifying the innards of the radio. Mine uses the original audio circuit of the 390, though one could feed the output of the PD to an external amp. A small audio preamp is included in the circuit to adjust the level going back into the 390. I have no experience with other auxiliary ssb detectors so can't offer anything on relative performance. I prefer listening to the 390 compared to my unmodified NRD-525 because the audio is better. Best regards, Dan.

From: DJED1@aol.com

Subject: Re: [R-390] Single Sideband reception with the R-390/R-390A

Thanks for the comments on SSB adapters, Dan. I'm really happy with my outboard SSB adapter for all the reasons cited (I did add the crystal BFO, per AI2Q). As Les indicated, you haven't solved the problem unless you've solved the fast attack AVC part of it- a product detector is not enough. My outboard SSB adapter does that, and it is integrated with the receiver so all controls and the carrier meter still work as intended. It always aggravates me to read Jan Skirrow's description of his outboard box, which copied my design, then says how mine never worked. But he left out the AVC circuit, and so needs to ride the RF gain to keep from overloading the detector. \$150 and no real improvement over how the stock radio operates! I've continued to play with the concept. I've breadboarded a circuit for synchronous detection, and will add that to the box if I ever finish my wife's "to-do list" for this winter. Incidentally, I built another version with a downconversion and 100 Kc filter for sideband selection, kinda like the CV-591. It worked well, and doesn't require offsetting the BFO to change sidebands (BFO is fixed at 100 Kc). However, the radio must be set at the 4 KC bandwidth, and so signals bleed through into the IF and meter circuit. I didn't like it as much as the original, so reinstalled the original box. I think the audio is better than my R4C, although the AVC is not as tight as the Drake. Ed

Subject: Re: [R-390] Sideband slicer

The R-390A has an IF of 455 kc. The Model A Sideband Slicer had an IF of 455 KC more or less, so it will work. The R-388 has an IF of 500 KC so the slicer may not work. You would have to change the frequency of the oscillator in the Slicer. I don't know if this is easily done or not.

>Since they have IF's out the back to you have to some wiring changes?

No, the IF Output of the R-390A is all you need to run the Slicer. HOWEVER.. the slicer may not be meant for the relatively high signal level provided by the receiver. You'll have to try it out. Some slicers were equipped with an IF Preamplifier. If I remember right, this is a little chassis with one tube that plugs onto the back of the slicer. If I remember right, the slider audio is routed back to the

radio and connected to the audio gain pot or some such thing. I suggest you use an external amplifier and speaker for that. OR: you can run the audio back to the diode load terminals on the R-390A. Do you have a manual for the slicer? I think BAMA has it.

Subject: Re: [R-390] SSB R390A on eBay

Something strikes me odd here about the mod...I don't think it's original or factory. Why would the BFO switch be labeled "LSB OFF ON BFO"? Strange..did they decide to crystal control/fix the LSB side but let the operator hunt for the USB side? I think this is a fixed (sorta) frequency BFO mod..not necessarily a SSB mod. For it to be a SSB mod it needs to have (IMHO) the extra module between the front panel and audio deck with a 6U8 or 6EA8 product detector (or modern equivalent of course), and the associated switching to preserve the AM/CW modes. My Motorola has this extra module. The pics don't give a clear view so I can't say for sure, but I think we just have a BFO mod here.

Chuck Rippel says the extra module is quite rare...I've seen/heard of a few...I don't

have a feel for how rare they actually are. Comments? Seems to be in reasonable physical shape though.

Subject: Re: [R-390] SSB R390A on eBay

If it's not factory who ever did it did a pretty good job. Used a PTO type connector to interface with the IF deck as seen in one of the photos showing that area. I would guess that's not a 3TF7 in the socket to the right of it either.... Is the schematic of the factory mod documented anywhere? I wouldn't mind taking a look at what was done.

Subject: Re: [R-390] SSB R390A on eBay

I think the labeling is understandable. Whoever did this substituted a 4-position switch and added LSB and BFO to the left and right of the existing lettering (perhaps because it is an engraved panel?). I would guess that "LSB" is just that, "ON" is USB and "BFO" is "regular" bfo operation. Just a guess, though. Either way, it's too rich for my blood.

I met Dick about 2 years or so before he died and we became close friends. I wound up buying his radio stuff from his estate after he became a Silent Key. The last time I saw him he was redoing the roof on his house in No. Hollywood at 86 years young as he said. When I left that day he asked if I wanted some Tangerines from his tree. I said sure, so he grabs a three legged orchard ladder and sprints up it to pick me some off of the tree. Anyway to the point. Yes he did the mods for the SSB on the R-390-A and had about 100 panels refinished with the SSB mods silk-screened on the panels. At that point in time I posted to a few of the reflectors that I had the components to make up the complete kit if there was enough interest. I received about 4 or 5 replies to the affirmative. I also had a bunch of Columbia tags also. Unfortunately in my move from CA to TX while I was laid up with a broken shoulder and a foot infection my brother in law decided that most of the parts and a lot of my radios were pure junk after I pointed out to him that they were salable parts, which he promptly sold for .10 a pound to a local junk dealer. Three 2 1/2 ton stake bed loads plus what the helpers carted off as scrap metal. Which also included nearly complete R-390A and some frames plus lots of modules. He was judge, jury and executioner all in one. That is the end of Airborne Engineering sadly to say.

From: "Dave Maples" <dsmaples@comcast.net>
Subject: [R-390] Slowing main tuning for SSB

All: With NOMEX inners and Kevlar outers, I bravely ask the following: I have paired my 390A with a Johnson Valiant II with SSB adapter. With 100 kHz per knob revolution, the main tuning for the 390A is a bit fast for SSB. Using an external SSB adapter doesn't solve this issue unless one uses the 8 or 16 kHz filter and uses the external adapter to move around within the filter passband. That kinda defeats the purpose of the narrow filters in the 390.

Has anyone ever added any sort of reduction gearing for the main tuning to slow it for SSB? I'm curious to see how other folks have handled this. I am thinking about a metal bracket secured to the front of the 390A using the three Phillips screws that are (a) above the LOCAL GAIN control, (b) to the lower left of the LOCAL GAIN control, and (c) to the right of the RF GAIN control. This bracket would stick out from the front of the 390A far enough to allow a Jackson Bros 6:1 or similar gear reduction device to be used on the main tuning shaft. The LOCAL GAIN and RF GAIN controls would have to be extended (no big deal there, I don't think).

By doing this this way, the modification could be completely removed if I choose to sell the rig. It's a fair amount of metalwork, but I don't see another way to add any sort of reduction in a way that can be easily reversed.

Subject: Re: [R-390] Slowing main tuning for SSB

One way is to center the tuning of the desired signal in the center of the passband of the filter of choice by "S" meter, then use the BFO pitch control to tune to the correct voice sound. Another way is to favor one side or the other in the filter passband, upper side of the filter for LSB and lower side for USB, and THEN use the BFO pitch control as above. Your problem is ONE reason certain R-390s had a vernier control on the BFO pitch control.

Subject: [R-390] Slowing main Tuning for SSB

I have what I believe is a SSB tuning assembly for the 390. What it entails is an extension shaft with a gear was mechanically coupled by a sleeve to the main tuning shaft. Over the additional shaft there was a small machined box that was mounted I think by 1 machine screw??? to the outside of the front panel.

A small knob came out the bottom of the new attached box. The small knob was attached to a worm gear which engaged the gear on the new extended shaft. Normal tuning could still be done by disengaging the worm gear by snapping the small knob to its second position. Fine tuning using the worm gear was like snapping a light switch into the engaged position. The old tuning knob just mounted on the end of the extended shaft. I have one of the assemblies. Contact me if you r interested after Dec 28th and I'll try to find it for pictures. It's Mil. Green - it looks great with gray.

Subject: Re: [R-390] R-390 AProduct Detector

There are several available, depending on how much modification you want to do. The limitation of the R-390 and R-390A for high-quality SSB reception are in two areas. First is that the BFO injection level is too low. The second is that the AGC is not optimized for SSB. Paul Lee was probably the first to address this. It involves adding a switch, replacing a tube, and some extensive wiring.

The second, and probably most popular is the 'Lankford' mod. Developed incrementally by several people, it does not involve extensive re-wiring, and addresses both the BFO Injection issue and the AGC issue.

A third one is a little black-box unit that a few R-390A's were fitted with. The wiring is unknown to me (anybody out there know?), but it fitted behind the front panel, and provided fixed BFO and, possibly a detector and AGC.

A fourth one is to add a separate SSB detector/BFO at the IF Out. Several Mil-Surplus detectors do this, as well as the Hammarlund HC-10. The latter has the advantage of providing notch filters and bandwidth filters, though it is expensive at about \$300. The latter option just got a lot cheaper if you have access to a reasonably fast PC. A lot of Hams are playing with a little device called a SoftRock. What this is is a IQ mixer/Detector that feeds a wideband (96 kHz) signal to your sound card. Designed originally as a direct conversion receiver for the HAM bands, several have experimented with it as an IF detector. At about \$20 per kit (and there is one designed for 455 kHz), you can connect it to either the IF Input, or the back panel IF Output through an attenuator. The result is a detector that with the help of your PC will do AM, CW, USB, LSB, ISB, FM, and about a thousand filter combinations, including notching. Add a diode and buffer circuit, and you can generate AVC to feed the R-390. I have documentation for all the above.

Subject: RE: [R-390] R-390 AProduct Detector

Hi, I built and use the ss PD that Alex posted - works fine with better agc than standard and a little better sound. It's not going to make a big difference in your 390 enjoyment unless you encounter strongly varying signal strengths and don't like fiddling with the rf gain. The agc in the ss unit does much better than the normal 390 on ssb and the detector itself can handle a bigger range of signal levels.

From: "Kenneth G. Gordon" <kgordon2006@verizon.net>
Subject: Re: [R-390] R-390 AProduct Detector

The very BIGGEST problem with installing any sort of internal product detector in the R-390(*) is the completely crappy original AGC system. Although it was probably adequate for the service for which it was intended, it is no longer adequate at all. As I mentioned here a week or so ago, there is an article in a recent issue of ER magazine (www.ermag.com) detailing an absolutely magnificent, simple, AGC system that completely rectifies all the known deficiencies of the stock system. Attack is almost instantaneous (611 microseconds), overshoot is completely non-existent, and audio distortion is very much reduced. The matter of low BFO injection can be taken care of very easily by the simple addition of more capacitance in the right place. At one time about 30

years ago, I installed a simple triode product detector circuit (stolen almost verbatim from Heathkit as used in their SB/HW transceivers) in an R-390. I used that 1/2 of the dual triode (12AX7?) that was normally used to feed the IF signal out to the BNC on the back panel. Despite the crappy AGC system, my mod worked quite well for SSB, and didn't seem to effect AM.

From: Mark Huss <mhuss1@bellatlantic.net>
Subject: Re: [R-390] R-390 AProduct Detector

Not sure this is such a problem as you think. Two ways to generate AGC is (1) RF Voltage at the Detector. (2) AF voltage after the Detector, often called AVC. For AM, Nr 1 is considered best, as it is not affected by the modulation level because it acts on the received carrier wave. For SSB, however, there is no received carrier wave. Instead, Nr 1 often will be driven by the BFO injection level. Thus Nr 2 is the preferred way of controlling receiver gain. You can get around this by tapping the RF level before the BFO injection, but older receivers not designed to receive SSB had no reason to do this.

With an External detector, however, things are different. If you set the receiver for normal AM reception, with a slow AGC time constant, the receiver AGC will act normally, substituting the sideband RF for the Carrier RF. It will be choppy and constantly varying in level as it is the modulation, but the Slow AGC time constant smooths this out. It would be the same as more modern receivers tapping the AGC voltage before the BFO Injection point. Attack time on the first syllable may be improved. And you have to have a long enough decay time to cover pauses between sentences. And you will have to use the receiver's filtering for most of the selectivity.

The beauty of the Softrock solution is that it has its own AGC, implemented in software, with a range of greater than 60 dB (dependent on the dynamic range of your sound card). Taking a worst case example of two closely spaced signals a hundred Hz apart, and ignoring the 0.1 kHz position of the Bandwidth control. Receiver AGC will be controlled by the stronger, unwanted signal, the wanted signal suppressed, say 30 dB by AGC action. By setting your external detectors bandwidth to, say 100 Hz, and off-tuning the external detector frequency (can you say 'Passband Tuning :-)'), the external detector's AGC will easily recover the

suppressed signal. Or we can use an alternate technique not seen often any more. Set up a notch filter in software to take out the offending signal. Where the Receiver AGC is set by the unwanted signal, the Softrock AGC is set by the wanted signal, the unwanted signal not affecting the Softrock AGC.

This is much like the excellent Hammarlund HC-10. In Hammarlund's case, they literally took a Hammarlund receiver, complete with bandpass filters, Q-multiplier, Detector, AVC, and Audio Amplifier and boxed it up. 455 kHz (430-520 kHz, set by a trimmer inductor) is taken in. Converted down to their 60 kHz IF whose gain is controlled by its own AVC, and detected it. I believe the AVC is available, but seldom used in practice.

I remember seeing someone who had a Drake 2B laying around unused. With a few wiring changes, he implemented an HC-10 clone. and Drake 2B receivers are going for about \$180 on EBay. The HC-10 is going for +\$300 on EBay. The softrock is by far the most expensive solution. \$20 for the Softrock, and \$700+ for the computer/Display/Sound card to use it. Of course, if you just happen to have a reasonably new computer sitting beside the R-390 that you use for logging/etc., the solution drops tremendously in price to about \$40 in parts (connectors, box, power supply, cables, and kit). Plus it adds passband tuning, linear detection, a multitude of filter options, limited scanning capability, digital recording, CW and Digital Mode decoding, Propagation prediction, even an Atomic Clock(if it is connected to the Internet). Heck, with a little breadboarding and some programming, you can do away with that pesky Zero knob by counting the three oscillators and sending the count to your PC via the serial port! An eight-input mux, three 74HC4046's, and a PIC will do that. Tap the oscillators with #30 wire-wrap wire wrapped around the tube under the shield.

From: DJED1@aol.com
Subject: [R-390] R-390 product detector

I've played around with a variety of product detectors- so here's my .02 for what it's worth. I started using the R-390A alone, and found I could copy SSB pretty well just by using the medium AVC speed. I then put in the pair of diodes to speed up the attack time, and that helped. Probably OK for casual listening. I picked up a bunch of CV-591As for \$35 each (ah- those were the days!) and used one for a while. The passband tuning was nice, as was the ability to switch sidebands. As I recall it didn't feed AVC back to the receiver, so the radio's AVC was still

operating. But I didn't really have room on the desktop for the converter, and I didn't like the lack of a speaker output, so I sold it off in the 1970s. A few years ago when I rekindled my interest in the R-390A I decided to design my ultimate SSB adapter, and set the following criteria: -no modifications to the radio- connect only to available rear connections -provide fast attack AVC to the radio -small and unobtrusive

I built an adapter using a 1496 chip, an amplified AVC circuit, and a tunable BFO. The unit takes the IF from the back panel of the radio, generates AVC voltage, and demodulates the SSB, providing audio. The audio is fed back to the radio via the diode load jumper, which is removed. A switch in the adapter allows the radio to operate normally for AM and CW. I was going to open up the AVC jumper and use only the adapter's AVC, but found the signal strength meter didn't work properly, so I just feed the adapter voltage to the AVC buss, leaving the jumper intact. The adapter provides the fast attack, and I set the radio to "slow" AVC. This is the best solution, in my opinion. The radio operates using all the normal controls, and the meter works normally, except you can see the fast attack and slow decay on the signals. Audio is controlled by the local gain knob. As with the normal radio operation, you need to offset the BFO depending on which filter bandwidth you are using, and you need to recalibrate when you shift the BFO. Audio is clean and clear for all signal levels, with a nice low frequency response because the adapter's audio is not band limited. I've added Alex's crystal controlled BFO, but since the frequencies are not set exactly for each filter bandwidth, it's a more stable solution but not as convenient for different bandwidths. Next, I undertook to do what I thought would be the ultimate adapter, somewhat similar in function to the CV-591. I had a surplus 100Kc crystal filter, so I downconverted the 455 Kc IF to 100 Kc, built a 100 KC crystal BFO, and added the same AVC circuit. The downconverter had two oscillators to switch sidebands. No more recalibrating when I switch sidebands. However, it was a disappointment. The receiver IF filter had to be set at twice the passband of the adapter, in order to pass both sidebands. However, the radio's AVC circuit operated at the receiver bandpass, so strong signals in the unselected sideband drove the AVC. I tried running the AVC through the sideband filter, but then the meter didn't work right. That was when I added the crystal oscillators to my original design, and have been using that now for a couple of years. Alex, AI2Q, has a clean schematic of this adapter for those who want to roll their own. Jan Skirrow sells a similar product detector, with a synthesized BFO, but, regrettably, without the AVC circuit, which is essential to good operation. I've lusted after a HC-10, but never have had the opportunity to try one. Having notch tuning would be nice, but I don't know what they do with the AVC. Ed

Subject: [R-390] SSB adaptors-R-390

One swallow doesn't make a summer, but looking over the flock that flew around a few years back, -one bird with potential stood out in my evaluation of SSB adaptors. I settled on the details of the box written up in ER by Mike Bohne KG7TR--- sorry I don't have the issue date as paper work I have didn't show it. . it is a 6BE6 prod. det, but its great performance on my subjective evaluation lies in the way AGC is derived, the efficient selectable hang time, and the levelling ability of the audio which is fed back into the R-390A. I would say that a read of the technical details would clarify some of the AGC problems that have been aired recently. The fact that NO mods are made to the rx is a plus but 4 tubes and attendant P/S make for a sizable package.-- so what--- so's the receiver !.I used a spare BFO from a R-390A as the injection oscillator which is easily reset for LSB or USB as the fancy takes you and with what ever filter bandwidth you select. Input is via the 455 khz output on the back panel. Mike makes the comment in his piece that the RFgain system works just like the ones used on most Collins and Drake xcvs. As a side issue I found that putting the P/S xfmr in the same box as the PTO cause FMing of the detected signal which I attributed to magnetic field from the xfmr influencing the permeability characteristic in the PTO.... probably no effect with a more conventional L/C circuit which Mike used. Like I said, it's the only aadaptor I've ever used yet appears equivalent in performance to any I used in ham gear over years. I commend the article and adaptor which I currently use . Someone on the list might have a reference to the issue number for those who dare ! Cheers

Subject: RE: [R-390] R-390 AProduct Detector

You and I probably hit the same web site (AMQRP) which originally sold the Softrock-40. It states the project is sold out. Beyond that, it has some issues. The page has a link to the "upcoming version 5" which (now incorrectly) points one to another useful and interesting software defined radio website (<http://www.hamsdr.com>).

Due to an email I received from Mark Huss (Thank you, Mark!) which indicated the existence of a version 6 of the Softrock, a lot of digging eventually led me to a Yahoo group for the Softrock project and it's users. That group is "Softrock40" and includes information on the current version, product availability, and purchasing instructions.

Subject: [R-390] W0BT and N6PY mods in ER Magazine

Good evening list. Recently, I decided to modify my R-390A based on the September 2006 issue of ER magazine. I made the following mods: <snip>

3. W0BT AGC mod. A big step but also well worth the effort. My R-390A came to me already with the Rick Mish SSB AGC Mod on the back terminals and the Langford AGC mod. Removing the Mish mod was no big deal but moving from an undocumented Lankford mod to the new circuit was tedious. There is a typo on page 32, item 6 (should always read 0.1uf) but the article is very easy to follow and mine worked the first time. <snip>

Over all result is a much better AGC system, a noise limiter that functions better, and a nice SSB product detector that sounds really good. <snip>

From: "TChirhart" <sparks@codepoets.com>
Subject: EAC R-390 factory modification that incorporates USB/CW/LSB

Does anyone know any any R-390's that were modified under contract that removed the BFO on/off switch and replaced the BFO pitch control with one control? I saw an R-390A, EAC contract that had this modification. A vertical 1 inch by 3 inch matching grey panel plate was installed over the two switches and only one control remained. It had a LSB CW USB position where the BFO pitch control previously was located. The owner indicated that this was a rare factory modification. Sorry no photos were taken. So was there ever a modification of this nature that was not an aftermarket add on?

Subject: Re: EAC R-390 factory modification that incorporates USB/CW/LSB

I have a Motorola that has the 6U8 module behind the front panel. Don't know about the "Mexican Military" story. The IF deck is EAC though. My version still has the BFO knob for CW, but has USB/LSB/AM choices as well. The IF deck has a new connector up by the ballast tube which connects to the module and the expanded mode switch. I've had mine for almost 15 years now. Works reasonably well. If it wasn't a factory job, it was a very well done depot mod. I'm not sure how rare it is or isn't though. That would be interesting to know. I think Chuck Rippel made mention of it on his website.

From: David Ross <ross@hypertools.com>

Subject: Re: [R-390] SSB-Modified R-390A

Does this describe the LSB-USB-AM-CW mod for the R-390A? "Mounted on a small L-bracket chassis, it consisted of circuitry featuring a 6U8 tube with two crystals and a USB/LSB selector switch. The original BFO switch was removed and the new assembly installed in it's place. A short cable fit into an 8-pin connector added near the front of the IF deck for power and signal output. The front panel was refinished, repainted and silk screened with new lettering for the USB/LSB switch" This is from the February 2003 issue of Electric Radio, page 32, article titled "Dick Walser Remembered". Dick is apparently the fellow who came up with this SSB mod. The article mentions Dick's company, Airborne Electronics and further states: "In all, Airborne remanufactured about one thousand R-390As. A large number of them were shipped to radio dealers in the (Los Angeles/North Hollywood) area. Not all of them went to the dealers. Todd Shipyards purchased ten radios that were to be installed in five destroyer escorts being built in the 1970's, and in the 1980's a mysterious Japanese entrepreneur purchased twenty R-390A's for his well-heeled clients in Tokyo. Most of their rebuilt radios were shipped to well-known 3-letter Government agencies. Some were shipped to countries in South America. R-390As that were under contract to Columbia Electronics received a new nameplate that reflected 'Columbia Electronics' as the manufacturer." Columbia Electronics does show up as an R-390A manufacturer on an R-390A FAQ at: <http://www.r-390a.net/faq-manuf.htm>

From: "TChirhart" <sparks@codepoets.com>
Subject: Update: EAC R-390 factory modification that incorporates USB/CW/LSB

The R-390A that I mentioned in previous emails back on June 4th has followed me home. I have photos of the unit but it does not appear to be the modified Mexican military version. An engraved panel has been added that covers the BFO Pitch and BFO switch and is 2 inches wide, X 4 inches tall. The markings for the plate that cover the Pitch control show "UPPER BFO LOWER" and the Switch shows AM CW/SSB. I do note that on the nomenclature plate, after the serial number 182X that the letter "A" has been stamped next to the SN and appears to have been added later. The SN on the rear of the chassis does not match the nomenclature plate. The rear number is 31XX and since the zero adjust knob and dial lock knobs have the marker lines I would say it has been to the Depot at one time or another. I have not fired it up but did test it prior to getting it. The previous owner used a light zip cord taken from a clock radio to power it up. Other than missing the top cover it is intact.

The PTO is a Cosmos, the other modules are EAC and the previous owner pulled the filter caps and have replacements taped in their place. I'll have to find a pair of caps and do it right. (Does someone on the reflector sell remanufactured cap kits or rebuilt caps?)

Does anyone on the reflector know of an aftermarket plate as described above that was marketed in the past? It really looks commercially manufactured and not the work that would come out of a trophy shop. This unit is of the same contract that is mentioned in the email excerpt I received below but is not the same mod. I would like to see a front panel photo of one of these 390's for comparison.

Quote: In November, 1998, Mike, KC8CU reported finding a R-390A where the BFO control had been replaced by a 4-position switch marked LSB-USB-AM-CW. A 6U8 product detector circuit had been added behind the new mode switch. This specimen appeared to have been based on a modified 1967 EAC unit from contract DAAB-05-67-CO15 (CO155) by Columbia Electronics, Inc. of North Hollywood, CA. Columbia Electronics' owner confirmed that they had indeed modified 30 R-390A receivers for SSB for the "Mexican Military". Unquote

Once I put on a proper power cord I'll fire it up and check it out. I'll try to post some photos when I get a website up and running, but if anyone knows of an area where you can post photos for no cost I'll upload them.

Subject: [R-390] 1967 EAC with SSB modification Photos

I loaded some images of the EAC R-390A that found its way home with me a couple weeks ago as reported on the reflector. I did receive various email responses to my inquiries that gave me some thoughts on the history behind this particular receiver, but it does not appear to be one of the Mexican military receivers. The additional front plate looks to be professionally manufactured. I will load additional photos shortly. As I mentioned in previous emails, the nomenclature plate has the S/N engraved and the letter "A" stamped to the right of it which indicates that the letter was hand stamped into the plate. Thanks to all that sent emails and particularly to Les Locklear for taking time to provide scans of photos and some potential sources of information on this particular receiver. I hope to have more time to go into this receiver in depth once the honey-do's subside. Has anyone out there in R-390 land seen a similar EAC in this configuration? Thanks 73 Tom K4NCG

From: Bob Camp <ham@cq.nu>
Subject: Re: [R-390] 1967 EAC with SSB modification Photos

A few quick observations:

- 1) The electrolytics obviously were done after the radio left military service. I would take care of them before I did much else.
- 2) The "ssb mod" appears to have been very nicely done, but I 'm betting it's not an official conversion. My guess is that it's a well done amateur modification. The gray jacket wire looks a lot like Belden. It's not something you see in a mil. spec. mod.
- 3) The radio is a bit dirty on top, it's doing just fine on the bottom. The power transformer seems to be missing some markings though.
- 4) Everything that should be there seems to be present. That's including the black tube shields. Looks like a nice radio - congratulations !!

From: Flowertime01@wmconnect.com
Subject: Re: [R-390] RE sensitivity below 8mHz

You are correct about there being little reference to aligning the first IF slugs andcaps. The circuit is assumed to work just fine. Thus it needs little attention.

In the RF deck alignment procedure there is one paragraph.

Z213 gets tweaked at 1250 and 7250.
Z216 gets tweaked at 1900 and 1100
L215 gets tweaked at 1100
C205 gets tweaked at 1900
C213 gets tweaked at 7600

As you do the RF octaves, you just remember to stop on the 1,100 1,250 and 7,600 as you go by and do the IF stages.

We just used the RF into the antenna input. Used the same generator level we used for the RF octave adjustments. Stop on the needed frequency and peaked the proper coils or caps.

You tweaked T207 once any where under 8Mkz
You tweaked T208 once any where under 8Mhz.

Any time you change the tube in the first mixer or oscillator you need to peak T207.

If your receiver does not perform as well under 8Mhz then the first mixer and

oscillator needs a look at. The receiver should have the sensitivity under 10uv for all frequencies. But the receiver does have better sensitivity above 8Mhz. That extra conversion stage under 8mhz takes its toll on the signals.

From: Flowertime01@wmconnect.com
Subject: Re: [R-390] 7 Meg low sensitivity

After the switch contacts are cleaned with some deoxit and if the problem persists consider pulling the crystals and doing their contacts as well.

Back when (68-75) we did have crystals go weak and would replace them. Just cleaning the contacts would not always bring a band back up to par but a new crystal would fix the problem. I can believe the crystals are still going weak and causing problems. We just all cannot have a spare set of crystals around to swap out and try just to see if that's the problem. If you have a one band problem ask here to see if you can get a known good replacement to try. Postage and packing will cost more than the part.

From: Jim Haynes <jhhaynes@earthlink.net>
Subject: Re: [R-390] AGC mod

I haven't studied the one in the Navships manual, but there is one in the September 2006 issue of Electric Radio. And there are some others that have been done with the intention of making the R-390A good for SSB without an external SSB converter. The general principle of these is to make the AGC fast on attack and slow on decay, so it holds the gain down in response to the envelope of

the SSB signal. Then they greatly increase the BFO injection level. If you have strong enough BFO in relation to signal you can detect SSB fairly undistorted with a diode detector. This is a lot simpler to do than putting a product detector into the R-390A. Some guy used to sell an SSB modification kit that required no internal changes. Consisted of a rectifier connected to the line audio output, and feeding into the AGC line. The idea was you would listen with local audio, and turn up the line audio gain to get some audio AGC. This was fairly ineffective.

From: "Dan Merz" <mdmerz@verizon.net>
Subject: RE: [R-390] R-390 SSB Product Detector mods?? Not A

Peter, I use a solid state SSB detector unit with my 390. It's outboard and requires no modification of the receiver and connects to the terminal strips and IF output on the back of the receiver. It has an AGC control built into it which is the main reason I went with this particular version in contrast to a more commonly available version without AGC. I couldn't see going to the trouble of adding such a unit unless it provided some AGC that alleviated knob twisting to handle strong SSB signals. My unit was designed by AI2Q, and I believe I have a schematic on file that I could look for if you are interested and contact me off the group direct. It uses 5 transistors and a 1496 IC with built in power supply, all built into a 5X9x2 1/2 inch box. The unit could be a lot smaller if one wanted to make the effort. I built mine using some old National tube BFO and IF coils - the original schematic used crystals for each sideband frequency. Instead of switching crystals, I turn the BFO cap between two marks for USB/LSB selection. It works great and I use it all the time with my 390 which is pretty standard otherwise. You could adapt the R392 BFO PTO available from Fair for the BFO as well if you wanted it to be "Collins" unit !! I wasn't interested in making any mod's within the receiver itself. I believe there are numerous tube mod's in the archives that take you in that direction.

From: Gord Hayward <ghayward@uoguelph.ca>
Subject: Re: [R-390] R-390 SSB Product Detector mods?? Not A

There are lots of outboard ones that use the IF out. No mods required and no A or non-A issues. Mine uses 2 balanced modulators with the split BFO fed 90 degrees shifted. The effect is SSB stereo. Of course it does nothing to the SSB signal but it really changes the noise. Instead of a hiss it sounds like a waterfall in 3D. Less tiring and almost pleasant. The AGC is likely a source of grief but there are mods available, or use the terminals on the back to supply your own from the

detector system.

From: DJED1@aol.com
Subject: Re: [R-390] R-390 SSB Product Detector mods?? Not A

I'd certainly recommend the AI2Q unit if you're up to building it. Alex based it on my design using a capacitor-tuned BFO. I've been using mine for several years and have done a couple of modifications. I'm happiest with the last, which uses a R-392 BFO coil as the oscillator. I checked the stability and it's just as good as the original R-390A oscillator. I modified my circuit to use Alex's crystal BFO several years ago, but I like the tunable better. It depends on your preference- the crystal is easier to use-just flip the switch. However, my crystal frequencies are a bit off for the correct edge of the 2 Kc filter so I lose the lows on one sideband, and are obviously not at the edge of the 4 Kc filter. With the tunable BFO, you can set it exactly to the edge of the filter. I had two objectives when I designed the SSB adapter, to make it work without and mods to the radio, and to provide both a product detector and a fast attack AVC. It works great and will handle very strong signals. The AVC is not quite as flat as my R-4C, but the original AVC on the R-390A is not very flat either. Unfortunately, this is not available except as a build-it-yourself. However, I can provide help if you have problems. Ed W2EMN (formerly WB2LHI)

From: "Dan Merz" <mdmerz@verizon.net>
Subject: RE: [R-390] R-390 SSB Product Detector mods?? Not A

Ed, my memory is poor. You reminded me how much help you gave me when I was trying to build the AI2Q unit and you provided a nice description and schematic in a Word document of the unit that was a precursor to his crystal controlled unit. Likewise, I've been very happy with the result. I bought a couple of the R392 BFO PTO's and used one in replacing the BFO in a Mackay 3010 and haven't gotten around to putting the other in a SSB detector but it's in the back of my mind. We moved about a year ago and only two days ago did I get around to hooking up the 390 with the outboard SSB detector - it and the radio worked just fine after the rest. best regards, Dan.

Content-Type: text/plain; charset="iso-8859-1"

I've owned a couple of the SE-3's older and newer (not the newest) versions. No, the modifications aren't "absolutely" necessary, but the AGC mods greatly improve listening on AM fading stations, it also allows listening to SSB without riding the RF gain. If you look closely, it is quite similar to the Lankford AGC Mod. Regarding the RT510/3TF7 Ballast Tube, there are more threads than you can possibly imagine on replacement modifications. I think there is no need for a fragile troublesome tube in the R-390A/URR, and replaced mine with great results.

What is the suggested approach for SSB modification for the R-390A.

Is the 2 diode modification worth attempting? I know it has been covered here more than once just wanted to solicit the current thinking on the matter ..

Date: Mon, 21 Dec 2009 22:46:40 EST
From: djed1@aol.com
Subject: Re: [R-390] Best approach for SSB mod on R-390A

Compared to buying a tube SSB adapter these days, the two diode approach will make the radio work pretty well on SSB. I used to just run mine on medium AGC, and that was OK. The two diodes made it better, but I eventually removed them because they affected the meter readings, and I got a R4C for my SSB work. Since then I've built a solid-state SSB adapter that works well (product detector and fast-attack AVC), so I occasionally use the R-390A to monitor the ham bands. AI2Q published a version of the adapter if you want to give it a try.

Subject: Re: [R-390] Best approach for SSB mod on R-390A

Tom, I concur with Ed's comments. I used the two diode mod for a while, worked pretty well except for agc and very strong signals which made manual tweaking of the rf gain necessary. I later made the outboard ssb adapter that Ed mentioned and that's been good enough for me. I've used it with both the 390a and 390. The 2-diode mod is very easy to do/remove. The outboard adapter is more of a project and needs a small power supply, which I built right on the adapter chassis. Dan.

Subject: Re: [R-390] Best approach for SSB mod on R-390A

Top of the heap....Sherwood SE-3. Treat yourself... www.sherweng.com

Next in line....PD-2 <http://electronicspecialtyproducts.com/>

Also there was a VE making a kit...Jan Skirrow, think he was a member here for quite some time. External Syncro/product detector. Worked real well as I understand. <http://skirrow.org/Boatanchors/TechTalk10.pdf>

Then there are the various mods you've read about that utilize the BFO to do SSB that are slight improvements on just using the radio as is. You will no doubt get many emails telling you it works fine just like it is...and in a fashion it does...it you desensitize the radio by backing down on the RF gain and what not... It works but

really...the radio was never designed to do SSB. There are also a few product detector mods which are probably worth looking into further. Problem is they are radio specific. You mod that radio and that radio alone works...but if you have several radio's the external approach is a better choice. (SE-3 or PD-2) Just my opinion though...

Subject: Re: [R-390] Best approach for SSB mod on R-390A

Hi, I would ask myself which of these detectors has any gain control built into it so you're not fussing with the RF control manually on strong signals. As far as I was concerned, this was the main reason for going beyond the 2-diode approach. I'm pretty sure the Skirrow kit doesn't, and looking at the SE-3 and PD-2 I see no specification that addresses this issue so I assume they don't either. Maybe someone with experience with these latter two detectors could clarify that point. But if fussing with the RF gain manually doesn't bother you, then take your pick for all the other features offered, or just stick with the 2-diode fix. The outboard detector that Ed mentioned and the one that I built provide a line back to the AGC for gain control based on level at the detector and use a product detector. Dan.

From: "Cecil Acuff" <chacuff@cableone.net>
Subject: Re: [R-390] Best approach for SSB mod on R-390A

The SE-3 is a complete IF/Sync Detector/Product Detector/Audio system, with an incorporated AGC system I'm quite sure. Should be no need to fiddle with the RF Gain. I've heard one of these things work and it's simply amazing. Brings any of the old Boatanchor radios up to date as far as detection of Sync AM and SSB. Good part is he offers a switching system that allows a whole rack of radio's to be routed through it with adjustments for the varying IF output levels found between radios such as the SP-600 and R-390 series. The PD2 is a new product and Jan would have to speak to the effectiveness of the need to fiddle with the RF gain.

My understanding of the issue with the RF gain on the stock boatanchor is more to do with the level of BFO injection. It's way too low for SSB work and the RF signal level has to be kept below the injection level of the BFO to keep things working properly. If you are not using the BFO for SSB detection the RF gain level should become a non-issue.

I would love to hear from anyone that might own some of these outboard devices...I know there were several of the earlier PD-1's out there and a few SE-3's as well....

Subject: Re: [R-390] Best approach for SSB mod on R-390A

I know the Skirrow detector does not have an AVC function, and so he says in the manual that you may need to ride the RF gain. But the real issue with the AVC is that you need a fast attack/slow decay in order to accommodate the rapid variations of SSB. With my adapter I just run the AVC voltage into the AVC circuit- the adapter provides the fast attack and the radio AVC is set on slow to provide the slow decay. I don't know about the SE-3-for the price, I hope it provides every function required.

Subject: Re: [R-390] Best approach for SSB mod on R-390A

I performed the 2 diode mod and I would characterize the results as a night-and-day difference over stock. It is extremely simple to perform and gets you probably about 90% of the desired result with less than 5% of the effort. Give it a try, it is just as easy to undo if you are not satisfied.

Subject: Re: [R-390] Best approach for SSB mod on R-390A

I use the diode mod as well and I think it works very well too. The article I read also said to parallel a few more PF with the injection capacitor which I also did. Without this, you may still find yourself backing down the RF gain to get rid of the distortion on the really strong signals. I also suggest that you avoid 1N4148 or 1N914 for the diodes. You need something with a higher PIV rating. I blew one of the diodes within a few days before I was advised of this issue by someone on this list. I switched to some different diodes and it hasn't hiccupped since.

From: "Drew P." <drewrailleu807@yahoo.com>
Subject: Re: [R-390] Best approach for SSB mod on R-390A

On the 2 diode AGC modification for SSB on the R-390A, Don (2002tii) wrote:

<snipped>

"Here are the AGC and BFO mods I've been doing for 35 years:

(1) Parallel R546 and R547 with solid-state signal diodes (1N914 or equivalent), with their cathodes toward V509A. This will produce asymmetrical attack and release times. (Attack will be very quick, release will not change.) To slow down the attack, if desired, put a resistor in series with the diode across R546 -- I often use 1 to 5 kohms."

I've seen a similar scheme which put the resistor in series with the time constant cap. I think that would allow the full AGC voltage to reach the gain controlled stages (relatively) immediately upon reception of a large signal transient, instead of being dragged down while the cap is charging. The effect might be to reduce the "pop" often heard on the leading syllable of a strong SSB transmission.

"(2) Install a new 20 uF film capacitor with one end to the junction of C548 and C551 (i.e., the grid of V506A). Disconnect the plate of V506A from J512 pin 15, and connect the free end of the new 20 uF capacitor to J512 pin 15 instead. Switch the wires from S107, terminals 9 (ground) and 7 (C551) -- ground to terminal 7, C551 to terminal 9. Install two, 2.2 Mohm resistors at S107 -- one each from terminal 9 (C551) to terminal 7 (ground) and from terminal 8 (new capacitor) to terminal 7 (ground). The AGC switch will then add C551 in parallel with C548 for Medium AGC and the new 20 uF film capacitor in parallel with C548 for Slow. The new 2.2 Mohm resistors bleed any residual charge from C551 and the new capacitor to reduce any pops when switching between AGC time constants. You can adjust the AGC release times by changing the values of C547 and 548 (Fast), C551 (Medium), and the new capacitor (Slow). I often use as much as 50 uF for the Slow AGC capacitor."

I just use the AGC "SLOW" position without these mods - still works pretty well. If doing so, it would be well to ensure that the 2 uF oil-filled AGC cap isn't leaky - mine was, and I replaced it with an under-chassis mounted polyester dielectric radial lead cap.

Don, do you see a disadvantage to using the original AGC integrator (tube) circuit with a good cap as opposed to disabling it and using larger caps as you did? Is disabling the AGC integrator tube mainly to facilitate gaining flexibility in selecting time constants?

"Mod (2) fixes the "audio disappearing" problem when switching to and from Slow AGC. (Note that this is a design "feature" [i.e., problem] -- If your 390A does NOT

have this problem, it's because C551 is not a capacitor anymore.) If you can live with the "audio disappearing" problem when switching to and from Slow AGC, you can omit mod (2)."

Ahhhh - sounds like Dave Wise's "Ending the Moment of Silence" mod. However, with all the mealy-mouthed preachers on the shortwaves nowadays, an occasional "moment of silence" can be a good thing!

"(3) To increase the BFO injection, replace C535 (12 pF) with 47-75 pF."

I didn't perform that part of the mod. If adding capacitance to increase BFO injection, it has been recommended to readjust the neutralization of the last IF amplifier stage to keep the added BFO injection from finding its way back through that stage and into the AGC IF amp/detector, where it would drive up the AGC voltage and desense the receiver.

ISTR where someone recommended replacing the 6BA6 BFO tube with a 6AU6 (12AU6 to all who use the paperclip ballast substitution) to obtain increased BFO injection. I don't know how the increase (if any) thus gained would compare with that obtained by upping C535.

Subject: Re: [R-390] Best approach for SSB mod on R-390A

My SE-3's oscillator is very steady. I wonder if there are good ones and bad ones. Also, without manual controls, the detector has to guess the operator's intentions, based on, say, tuning rate. I don't like machines trying to read my mind, because they usually get it wrong. For me it's better to have direct hands-on control. My only complaints have been the lack of a noise limiter and lack of a 5kHz notch filter in addition to the 10kHz filter. I've bookmarked your recommendations. Sometime I'll build one or more and report my experience using them vs the SE-3. Or if anyone local has built one, let's get together and try it out next to my SE-3.

Subject: Re: [R-390] Best approach for SSB mod on R-390A

I guess many of us are just not as demanding...and I approached this from the

perspective that it is the best of what is commercially available at the moment. There's no question that a better box is within the realm of design but nobody has stepped forward with one that they are willing to build or kit for the receiver enthusiast. Even most AM Sync detectors included in commercially available receivers are lacking in performance. The Drake R8B being one of the best...but it's not in production. The Icom R-75 is a good radio but the AM Sync detector is flawed right out of the gate...and with mods barely approaches the Drake. That said using most of these radio's for IF/Detector/Audio sections for the R-390 series comes with the limitations contained in the radio selected. They all cost as much or more, new or used than the SE-3. But that said they are all better performers at AM Sync detection and SSB then the R-390 alone...or even with the simple mods like the two diode deal and or AGC mods. At least that's my opinion...

From: "James A. \ (Andy\) Moorner" <jamminpower@earthlink.net>
Subject: Re: [R-390] Best approach for SSB mod on R-390A

This is a complex subject, but I will try to give 2 short answers:

(1) In a fully-analog design, what you do is design a PLL with multiple FET-selectable loop bandwidths. Generally 2 (narrow and wide) is enough, but I have seen as many as 5. The trick is deciding when to switch from "hold" (very narrow) to "capture" (very wide). There is generally some kind of signal-to-noise detector that compares the amount of signal in a wide band to the amount of signal in a narrow band, but the circuitry gets pretty baroque very quickly. It is hard to make this design work reliably over a wide range of operating conditions. The PLL tends to get sucked into nearby hot stations, or gets stuck holding in noise after the transmitter drifts off one way or the other.

(2) The classy way to do it is put a computer and DSP in the loop where the oscillator is tuned with a D/A converter from the computer. The computer and DSP do digital spectral analysis and look at the signals all around, then decide what number (frequency) to stuff into the D/A, and consequently what the oscillator frequency should be. This can be made arbitrarily smart, although more often than not it is still pretty dumb. On some of the \$\$\$ receivers, this "digital detector" is pretty good, like the high-end R&S offerings these days. Not for the casual listener, of course. If you have enough DSP horsepower, you do it all digitally with no hardware PLL at all. Being a DSP-head, this is my preferred implementation, but it takes a lot of careful DSP programming to make it work well.

Subject: Re: [R-390] Best approach for SSB mod on R-390A

I think Ten-Tec uses a DSP implementation in the RX-340 and 350. Les can report on both as he has owned each and still has one. Last I heard it was good but still not up to the Drake R8B level...unless I misunderstood...which happens more frequently these days.

Date: Sun, 3 Jan 2010 20:03:10 -0600
From: "Les Locklear" <leslocklear@cableone.net>
Subject: Re: [R-390] Best approach for SSB mod on R-390A

Actually, the RX-350 sync detector is superior to the RX-340. Having had both side by side for a couple of months, I sold the RX-340. The 350 has good audio, better sync, better noise reduction, better notch filter. Too bad they decided not to keep selling them. The R8B sounded more mellow, but I prefer the 350 1 hz readout and the remote keypad tuning knob set-up.

Most people that own or owned the RX-350 don't understand the filter scheme or how to properly implement the synchronous detector. It also sounds better than my NRD-545 and the DSP noise reduction is waaaaay better than the 545 which is not very good in that regard.

From: "Les Locklear" <leslocklear@cableone.net>
Subject: Re: [R-390] Best approach for SSB mod on R-390A

Yes, you can use DSB on the RX-350. Some users on eHam and the RX-350 Yahoo group gave it low marks, then changed their tune after figuring out the not so good filter implementation. In AM modes, the displayed filter values were doubled, which widened the passband and made the sync detector lose lock.

An example, instead of say a 5.4 khz filter (which is actually 10.8) one can use say the 2.7 khz filter (actually 5.4 khz) and use the am upper or am lower sync detector, dial in about + or - 1350 hz (that is how the PBT is displayed) and the sync detector is wonderful. If a station is totally in the clear, use DSB and the 8.0 khz (actually 16.0 khz) for really sparkling audio.

As with any receiver, there will be those who like it and those who don't. I guess that's probably the reason for owning more than one. Although these days, my collection is the thinnest in recent memory.

I'm retired and with the sunspot cycle, I haven't listened much of late. The weather is supposed to be in the low 20's tonight, maybe I'll fire up the SP-600 and HQ-180A to keep the shack a bit warmer.

Subject: [R-390] R-390A Product Detector Schematic available

Was that the detector design based upon the W1KLLK "Updating the SP-600" article from August 1970 QST? I have another schematic that would have required about seven different interconnects to the SP-600 to add a product detector and SSB to the SP-600. That was something I was working on when I compared the differences between the SP-600 variants and was looking at making a plug in module to add functionality. It has a 12AU7 as a product detector and a 12AT7 as a carrier oscillator.

Subject: Re: [R-390] tube based product detector.

I'm hesitant to say anything due to my lack of expertise with this... Believe there have been several things in Electric Radio and Hollow State News, but will have to look them up. Some people take the position of keeping the R-390A "pure" and build an outboard product detector or sync detector that hooks to the IF output and either has its own audio output or feeds back into the receiver's audio stages. Besides the product detector you need to tackle the AGC problem. There are a number of mods that involve using diodes in the AGC circuits to get fast-attack, slow-release action. It's harder to put a product detector into an R-390A than it is with some less-modular receivers, because you have the limited number of connector pins on the IF module. Typically the product detector mod requires putting in a relay to switch the audio between product and diode detectors, operating the relay from the BFO power. You can learn a lot by googling for Dallas Lankford, and in particular www.kongsfjord.no and click on "The Dallas Files" Once you get the AGC modified you can do pretty well without a product detector by increasing the BFO injection. The reason a diode detector doesn't work well with SSB signals is that the BFO level is insufficient.

From: wa4aos@aol.com
Subject: [R-390] 390A AGC

I am working with different AGC mods, 5 so far, that I have found on the web and in

ER. The Lankford mod looked most promising initially but I had problems with it bowing diodes but fairly decent AGC when working. Recently I found, with the help of Ray at ER, the W0BY mod listed in issue 208 of ER and it looked very promising as well, however, it still pops on loud signals going quiet. A good example are the morons who tune across the bands with full power, especially annoying if you are coping CW with headphones. I have noticed it on strong SSB signals as well. The article in ER seems to indicate this should not be a problem but yet it is and on 3 different modules wired correctly; perhaps there is something external to the mod that is affecting this AGC mod. I am working with late run EAC modules presently and was wondering if others had had success with an AGC mod that REALLY worked well. I will say that the W0BY mod does work much better than stock 390A AGC.

The Lankford mod as listed on the web is kind of tricky to follow as listed from his hand drawings but I have made many notes and easy to follow schematics. If I get the diode problem resolved, I will release my notes to the group if anyone wants them. I tried to contact Dr Lankford but he is not available and I can only ASSUME he would not mind if I offer help to clarify his notes as well as my own experiences and documentation.

I found the article in ER to be very well written and easy to follow but again that author was not available for questions or comments. Maybe they found something more worthwhile to do with their time instead of playing with 90 pound radios; bass fishing comes to mind. Hi.

I may try increasing the PIV of the diodes that were in the Lankford mod but to date I have had 4) IF modules blow diodes from that mod after some use. Perhaps implementing SSB compatible AGC with the 390A is not necessary but the receiver has so much going for it that I want to go a step further. I know I am preaching to the choir. Hi Any thoughts would be appreciated. Regards, Glenn WA4AOS

Subject: [R-390] Mod discrepancy

I am working on an Amelco R390A receiver that has had the Capt. Lee Product Detector Mod installed. When I got it, it worked for a while and then just quit. I checked the as-built against the circuit published in the 2009 Y2K 21 Century Reference Manual (so many names) and found the circuit to be identical in all but one area: The capacitive network outboard of the Z502 BFO Pitch unit is different. The original circuit diagram calls for a series 100 pf cap, C526, between pin 1 of the Z502 and pin 1 of the 6BA6W shunted to ground with a 5 pF cap, C527. (Pin 1 of the tube also has a 150k resistor to ground.) The Y2K mod schematic calls for the same configuration but the cap size(s) are 0.033 uF. (Only one cap is labeled so the intention is not clear.) Does anyone know about this change? Has anyone had difficulty with this circuit? I have no voltage chart for the 6BE6W replacement tube (after socket re-wiring) and the 455 kHz peak voltage is around 20 mV when the BFO is engaged. Is this correct?

From: Bill Wilson <we509w@yahoo.com>
Subject: [R-390] SSB mod

Currently I'm restoring a Collins R-390A that a friend of mine salvaged from the landfill. The AGC circuit has the SSB mod that works great for SSB with no distortion or complaints. The issue I am having is that on regular AM listening the volume is very low and sometimes the audio on some stations is only heard by turning up the local gain fully clockwise. This particular mod was done by

removing R545 (100K) and removing R546 (180K). Instead of R546 a diode was installed going to pins 1 & 2 of V509A (AGC rectifier). R547 (220K) was reduced to 10K. Spot checking some resistances indicated a 1 meg+ resistance on pin 2 of V504 which should be about 280K with the AGC in the "on" position.

Any hints on getting the AM audio (AGC on) back up a few notches short of scrapping the entire SSB mod would be welcome. Thanks in advance,

Frank wrote:no idea how to get that turned into a double side-plated through hole PCB.....

OK, check out EAGLE sold by Cadsoft. It is a graphical layout editor that can be used to help convert a schematic into a PC board layout, so that any low volume board maker can employ to make you a custom board. It has a steep learning curve for us casual users, but not impossible. My son designs controller boards for solar, and has used it extensively (shameless plug); and I am impressed with the results.

Of course, with my limited background, I just haywire stuff onto ready-made \$3 DIP boards from Fry's...

Subject: Re: [R-390] Suggestions for SSB adapter for R-392?

I guess if I was in the market for a new adapter I would consider the Sherwood Engineering SE-3 MK IV. A great many of the neat features are built into the box. <http://www.sherweng.com/indepth.html#features> Right now I have a TMC CV-591A that probably generates more heat than an R-390. I keep it because it can work on either R-390A or the SP-600. For the other receivers, most have USB/LSB/ISB capabilities but they "are not" classical boat anchors, just premium receivers.

If you were to go out and buy a restored CV-591A you could spend as much as the price of a new SE-3. If you are trying to keep your setup as "period authentic" then the CV-591A is probably one of the better ways to go.

I do not have too much faith on the inboard SSB mods to the R-39x series. Most are real compromise circuits. A few years ago I built an add-on box for the SP-600 that put the circuitry from a JX-21A into a JX-17. It was more effort than it was really worth. I traded that radio for a Cubic R-3030 and stuck with the unmodified, stock JX-17.

From: Tisha Hayes <tisha.hayes@gmail.com>
Subject: [R-390] SSB Adapter Kit, Making your own boards

If you did not have to worry about plated through holes you could use a standard photo resist etch on a double sided board. It just means that after you drill component leads you will need to apply solder to both sides of the board to make the component lead into a "via". You may have to add "via's" if there are spots on the board where they are called for (through holes, component leads, double sided soldering and clip flush).

I have gone the commercial PCB app before and had to satisfy the minimum purchase quantities. At least when I did it, I ended up making six circuit boards when I only needed one and the total cost came to around \$200 (3 full boards, cut in half to make six discrete boards).

Photo resist will be much easier, cheaper and faster. You will just need to contend with the vias

From: bonddaleena@aol.com
Subject: [R-390] SSB adapter

Hi. I have a CV-591A on my '67 R-390A. It sounds great but still needs an audio amp.

I just wanted to say that before I purchased the 591As, I had an SSB adapter by the chap here in Florida, ESP Electronics. It works excellent and is very well made and small. I have the PD-1. He is now selling the PD-2.

I was fortunate, because I was able to purchase the 2 different sets of IF crystals. I moved the PD-1 to my 51J-3. It has a 500 KHz IF, where the 390A is 455 KHz. I was also fortunate that I was able to purchase the front artwork that states "51J Receiver". It also works excellent on the 51J-3.

The 'only' small issue is that I have the IF gain in the 51J set a wee bit too high and the audio is slightly distorted at max RF Gain. The 51J has never failed to amaze me with it's excellent performance. Super sensitive receiver. These 'problems' are easily addressed in both the receiver and the PD-1, I just have too many higher priority issues.

(especially since my 220 VAC drop took a direct hit one week ago today. Ah Florida, the 'Sunshine State', and also 100 miles from the "lightning capitol of the

USA".....)

Subject: Re: [R-390] SSB adapter

I work in engineering for a TV station.
We use a number of Wohler audio amplifiers for monitoring.
These are typically 1 RU in height and require 24 V either AC or DC to operate.
The inputs can be XLR/RCA/Phoenix.
These amplifiers are high fidelity and magnetically shielded.
There are a number of these on EBay now in the \$100.00 range.
There is at least one group of 2 for \$100.00.
The amplifiers that we use are AMP-1A and their variants.
I personally own a 12 channel AMP-1A that I bought on EBay.
These amplifiers can be loud.
The only controls are volume, balance and channel if multi channel.
These, for me, make a good amplifier for our line level boat anchors as the input is line level.
If you do buy one, make sure that the one that you get is for analog audio.
Wohler makes analog, AES and SDI audio amplifiers.

From: Tisha Hayes <tisha.hayes@gmail.com>
Subject: Re: [R-390] SSB adapter

I think that audio quality on almost every piece of repurposed military gear is going to be deficient when it comes to leisurely listening. Either it ends up being the limitations of the components stuck in the audio amplifier chain or a bandwidth/

linearity issue in the IF.

We have a little of both.

In each of my receivers someone had been at them with a magic screwdriver before me and took the stagger tuned IF and dialed them all down to 455.0 KHz. It made for real good IF selectivity (a bit too good) as the audio recovery chopped off the high frequency response. Then there is the typical "old cap" issue and while you are in there, making a few value changes to open up the low and high frequency response.

Many folks are mystified by the 600 ohm audio output as well.

I have not screwed around with the Cv-591A audio circuit. Then again, SSB is not something I want blasting through the house either.

I have ceased to use the R-390A as my amateur radio receiver and it is used more for weak signal utility monitoring and SWL listening. Much of the utility monitoring is USB (maritime, aviation, military, etc..).

For fun, BCB I still use the SP-600, I guess the only way to beat that audio quality would be to get another Telefunken console radio.

Since this thread has started I have been mentally reviewing my use of the Li family CV-591A and wondering if there may be a better way to go. (A.K.A. Sherwood SE-3) as it would add synchronous detection for BCB/ AM. I like PLL circuits ever since I built a SCA decoder back in high school.

Subject: Re: [R-390] Suggestions for SSB adapter for R-392?

I've heard nothing but good about the Sherwood units but have never had the experience of one. One thing I have done, that I've seen mentioned here, is use an SDR to tune the IF out of the 390A. In my case it's a Winradio 303i, but I imagine it will work with any SDR capable of tuning to a radio's IF, as long as you can get the IF out of the receiver. Then I can use the demodulation of the SDR for whatever mode I want. I can even disable the winradio demodulator using a command line switch, leaving me with just tuning control of the winradio. I can then start up power SDR from flex or any other program that will work with I/Q inputs. Winrad is another one. These have a few more features than the winradio software, like noise reduction and such.

Kinda kills the whole vintage thing, but it does a good job with just about any signal, and gives me a panadapter to boot.

From: Grant Youngman <nq5t@tx.rr.com>
Subject: Re: [R-390] Suggestions for SSB adapter for R-392?

The cv-591 is, in my opinion, about the worst of the lot. I got rid of it. Sure, it looks the part, but just doesn't make the grade.

CE slicers are great performers. The Sherwood is exceptional, but absurdly priced as an SSB adapter only (even though I wouldn't part with mine for other reasons).

The HC-10 is ok, and if you can find one that doesn't require a second mortgage (good freaking luck!!), the SPC-10, which is a rackmount MIL version. The HC-10 local oscillator tends to "pull" a bit on strong signals because of how AGC is applied to the mixer/osc stage. SPC-10 may have the same problem, but I wouldn't know for sure since I haven't owned one.

For a 455 IF, it's worth looking at the PD-2 from espelectronics.com. The original PD-1 got good marks. Don't own one, but the price is right. It's crystal controlled, so you can't shift it to the edge of the passband.

From: David Wise <David_Wise@Phoenix.com>
Subject: Re: [R-390] Sherwood SE-3 Mk IV

I've used it with the R-390A and with a Hammarlund SP600. It's plug-n-play with the R-390A. Early SP600's put out way more 455 than late ones or R-390A's, so if you wanted to go back and forth, you'd have to tweak the SE-3's input attenuation trimmer each time. I modified my SP600 to the later spec, and I don't have to do that. I absolutely LOVE mine. It's like magic on deep fades.

From: William A Kulze <wak9@cornell.edu>
Subject: Re: [R-390] R-390 Digest, Vol 102, Issue 7

One approach that I'm using, and I've seen someone else mention it, is connecting the IF out to an SDR. You have to run it through some attenuation, but it will give you whatever modes are built into the sdr. I've been playing around with this for a while and I think I've got it pretty close to where I want it. I found that I can use the sdr panadapter to find good sweet spots for both IF and RF gains. You can see when you start introducing noise with the gain too high. The 'S' meter on my SDR (winradio g303) can be selected for microvolts, and I've got it to where the meter pretty well matches (close enough, anyway) to what my generator is putting out. I've found it to work best with the R-390a in MGC, utilizing the agc in the sdr. The two AGC's together wasn't as pleasant to listen to.

I can use other dsp programs with the winradio, and the one Simon Brown (HamRadioDeluxe) is working on (SDR-Radio.Com) has, among others, SAM, ECSS (upper, lower or both sidebands), and also has a pseudo stereo audio mode that is interesting and seems to improve legibility in some instances.

The audio quality depends on what you want to run it through, but it easily overcomes the one weakness of the R-390a. With this I can enjoy all the signal grabbing of the old rig and fully enjoy whatever I'm picking up with it.

Of course, this completely kills the 'vintage' equipment setup. :-)

From: Les Locklear <leslocklear@hotmail.com>
Subject: Re: [R-390] KIWA MAP unit on an R390A (similar to a Sherwood SE-3?)

I have used both, they are different in several different ways.....both use the 455 KHz if out, the Kiwa uses synchrophase detection, which is beneficial in weak signal detection and has two bandwidths typically 6.6 and 3.0 KHz (depending on the cascaded filters used for that particular unit). The Sherwood is a true synchronous detector re-inserting a carrier and locking on to it and is better on fading (both rapidly and deep fades) than the Kiwa unit. I have used the Kiwa connected to the if output and then connected the Sherwood to the 455 KHz output of the Kiwa Map unit which is post filtering. That makes for great audio albeit at a greater cost and is somewhat redundant.

As mentioned I have used that particular set-up with R-390's R-390A's, and R-725, multiple SP-600's and other receivers. I now only use the Sherwood SE-3 as the Kiwa was almost meaningless with my Icom IC-746 and JRC NRD-515 that has 6 filters and the Sherwood audio buffer board. I presently use the Optimus (Radio Shack) Pro X7 metal cabinet speaker which gives great highs and decent bass response.

Rather, it would be a downconverter, from the receiver's 500kHz output to the SE-3's 455 input. It's intriguing that he would choose that approach. I imagine he tried bending the VCO; I wonder what went wrong? Or maybe just prefers an extra board to hacking the main one.

Subject: Re: [R-390] CV-157

Well they are interestingly complicated. And they certainly are boatanchors. Even without the pwr xfmr it'll be 100 lbs. I really enjoyed restoring mine and learning all about it. Your friends will definitely be amazed watching the AFC motor do its thing. And being able to do simultaneous USB and LSB is kinda neat. But practically speaking the CV-591 is much much easier to restore and operate and move around. I have both hooked up and don't really hear any difference in voice quality. The CV-157 is a star because of the AFC and ISB capabilities but that's not anything you can make use of on the air today. Value? I think I paid \$100 ea for the two I have. One was local and the other cost me another \$100 in shipping. Basically the value to the other guy is what he could get parting it out. If you like technical challenges and enjoy learning new circuitry it is a great project even if the CV-591 is much more practical. My opinion for what it's worth.

From: djed1@aol.com

Subject: Re: [R-390] CV-157

I never had one, just some CV-591As. My understanding is that the '157 is a monster with 50 or so tubes, and was intended to process TTY on separate sidebands. So it has all the capability to simultaneously demodulate both sidebands, and, unlike the other converters, has an electromechanical system to

tune out any drift. The tuner may require a reduced carrier. Pics of the thing show IIRC two full rack panels. It's certainly a novelty, but it will be a LOT of work to get it up on the bench and get it working.

From: "Bill Hawkins" <bill@iaxs.net>
Subject: Re: [R-390] CV-157

What Nick said and some caveats.
The two rack panels are joined by a thick cable with no connectors.
You could separate them if you have infinite patience and time.

The missing power transformer is a deal breaker if you want to restore it. Quite unique. Speaking of unique, the mixer tube that brings 455 KC down to 100 is rare. Don't remember the number, now. The creep that sent mine had stuffed it with arbitrary tubes and put it in a single cardboard box with peanuts. The box was broken, peanuts mostly gone, and something heavy had smashed the 100 KC transformers in a corner of the upper chassis. Never did get it working, someone else's problem now. Lost several hundred dollars learning that lesson. Shipper wouldn't pay because of the crappy packing. Guy who sold it wasn't rational. The auto-tune mechanism requires some carrier in the SSB signal, which is unlikely these days. The 157 was part of a system that sent eight channels of TTY data, four on either side of the carrier. Good luck finding a signal like that in today's digital comm. Other than that, it's a real piece of high-tech history.

Subject: Re: [R-390] EAC SSB Conversion

I have a Motorola receiver that I purchased about 20 years ago now from a seller in Southern California. It is all Motorola with the exception of the small sub chassis behind the audio gain pot that contains the 6U8, 2 crystals and associated circuitry, and a modified EAC IF deck. The IF deck mods (that I can see) are the addition of a multi-pin connector (similar to the connector used on the PTO) and cable that takes the signals to the mode switch and takes care of switching the crystal BFO in and out of the circuit, and signal routing.

I can't say for certain if there were any AGC changes made because I haven't taken the time to trace it out. My perception is that there were none. There is still some need to "ride" the RF gain to prevent overloading on peaks.

There are no other markings on or in the radio to indicate that Columbia (or whoever else for that matter) did the mods. The front panel was professionally re screened with added mode positions. Unfortunately, I didn't ask or get any information on its past when I bought the radio. I'm happy to answer what ever questions I can.

These panels are the result of Columbia Electronics work in updating and restoring R-390A's for certain 3-letter US govt. agencies and for a few Latin American countries. I have several of the Columbia Electronics nameplates that I purchased from Dick Walser who was the prime sub- contractor doing the work..

He and his business partner designed the module that is an add on to the IF deck which produces the capability to switch from Lower SSB and Upper SSB. Somewhere in my files, I have a circuit drawn by Dick, but it is also available in PaoloViappani's book, R-390-URR - R390a-URR handbook. The book, written in Italian, appears to be available from: Amazon.co.uk.

I also have one of the panels designed by Dick with the nomenclature you describe. Dick Walser, in North Hollywood, CA, was the subcontractor in that work.

Subject: Re: [R-390] Unusual ? Front panel

It is curious that by now no one appears to have translated the Italian description in English along with a schematic and parts list. This lack of information in English begs the questions:

- a. Did the conversion work as hoped and work well?
- b. Was it worth the effort vs other schemes?
- c. Does anyone know?

From: Les Locklear <leslocklear@hotmail.com>
Subject: Re: [R-390] Unusual? Front panel

There are a couple of variations of the modification along with the 6U8A tube mounted inside the front panel, others with the modifications on the audio deck along with the 6U8A tube.

I do have the "Official" modification that EAC did on the original mod if anybody cares to see it. Reply off the list if you would like a schematic of it.

I have a Motorola with the modified IF deck and added module as well as the schematic from Paolo's book. It is quite clear, translation isn't really necessary to make sense of it, although I'm sure a translation would be helpful. Its a simple crystal oscillator using half of a 6U8 with two switched crystals. The output is injected when the mode switch is placed in the USB or LSB position. In SSB, the IF signal is routed to the second half of the 6U8 which is wired as a product detector. For AM/CW, the module is switched out and the IF signal is routed around to the stock detector for AM/CW reception. The switching scheme is as complicated as the module (not).

As far as performance is concerned, it does a better job in my opinion than a stock 390A..however I haven't been able to find any modifications to the AGC system, so that fact still needs to be addressed in any SSB conversion attempt. Never the less, it is quite convenient to be able to switch sidebands from the front panel. The audio quality is still superior with the product detector in my opinion.

You will also note that there are no changes to the filtering scheme...that is the filters are still AM/CW, and not LSB/USB which would be another improvement in receiving SSB.

Subject: [R-390] Restoration questions

Hi All: I'm currently in the process of refurbishing a '58 vintage Motorola with an EAC IF strip. I've finished cleaning it up and going over the mechanicals. So far I'm well pleased as it's quite sensitive and mostly everything seems to be working fairly well. On this unit I've noticed that the function switch has an unmarked, extra detente beyond "CAL". Functionally it behaves like MGC. Wattup wid dat? Secondly this unit seems to have a surplus of gain and readily overloads unless one rides the RF gain. It's particularly annoying on CW. Is this normal or an issue? Other than a rough check of the front end and checking tubes I really haven't gone through an alignment. So far I've checked tubes in the if strip and replaced C503. BTW, thanks to those who assembled the Y2K manual, what a resource!

From: Barry <n4buq@knology.net>
Subject: Re: [R-390] Restoration questions

That last detent is for an optional squelch circuit. Sounds like the IF gain needs to be adjusted. It's easy to set it too "hot". There should be info in the manual for setting it. Congrats on getting it refurbished.

Subject: Re: [R-390] Restoration questions

> That last detente is for an optional squelch circuit.

And there is or was a detent setting plate at the front of the detent part of the switch to prevent the shaft from going to that position if the squelch parts/system is not installed. There are one or two blank plates on the IF module if the mod is not installed.

Subject: [R-390] Softrock Lite II 455KHz

Over the past few years I had been using an FRG-7700 tuned to 455KHz for a SSB converter. I have fixed multiple CV-591 but have never been overly impressed with the sound quality.

This year at Dayton I spent the stately amount of \$21 for a Softrock Lite II kit. I finally got around to building the thing this weekend, I can say that I am totally impressed with the performance. I am using it with a Dell OptiPlex 755 I bought at

Micro Center at as a refurb with Windows 7 for \$260 and version 2 of Simon Browns SDR-Radio. So even assuming the eBay price for a CV-591 ranges from \$250 - \$500, I think the softrock is a great solution. I know this is heresy but this just adds a whole new dimension to my 390 experience . <http://v2.sdr-radio.com>

Subject: Re: [R-390] Softrock Lite II 455KHz

I have been using HDSDR (free) and the 12 KHz out of my TS-2000 (free) and I also converted the 455 out of the R-390A to 12 KHz (free from the junk pile), fed it into my soundcard (SB but I don't think it matters as long as it will do 44000 KHz or so) and as far as AM it's pretty impressive. It doesn't get mashed by the local audio chain. Much better than stand alone systems. But I wouldn't use it for SSB or CW, the delay is to much and hard to tune. AM is nice because you can immediately adjust the BW to what ever you like and watch the BW and signal while you're doing it. Only limited by the filter in the system and your audio amp/speaker system, 10 KHz for the TS-2000 and 16 KHz for the R-390A I'm still trying to figure out the DRM for DReaM. It may require a license or virtual system, not sure.

From: <chacuff@cableone.net>
Subject: Re: [R-390] How Much for a Sherwood SE-3 ???? - HOLY COW

The truth is the market sets the price for items being sold and the reality is Ebay has become the market in many cases. When I have something to sell, for the most part that is where it goes because there is no other place to get that kind of exposure and where the price ends up nobody really knows. Sometimes it's a big surprise. The opposite happens as well...many times a fellow will throw something up on Ebay with an outrageous price and it won't sell and the price keeps coming down until it gets with the realm of reasonable and maybe it sells or maybe he just pulls it off and keeps it. Either way the market takes care of it.... It's the same deal when I see \$3500 R-390A's up there...crazy...until someone buys one..and it happens! Keep shopping hamfests...that's the last holdout for deals like the old days....

From: Bob Camp <ham@kb8tq.com>
Subject: Re: [R-390] How Much for a Sherwood SE-3 ??!!! - HOLY COW

Solid state "stuff" changes a lot year to year. The SE-3 has been around for quite a while. There's no doubt that one *could* duplicate it with more modern parts and *maybe* improve things a bit. The problem is indeed exactly the one you mention. With all the PC/ sound card based solutions there's a pretty narrow customer base for a high(er) priced stand alone box. My guess is that you might sell 5 or 10 a year at \$600. That could double at \$300. Setting up and running a business (and doing support) for \$3K a year is not a great proposition. Yes, I have an SE-3. They are a great box. Everybody should have one. I'd still bet that the number sold was pretty small.

Subject: Re: [R-390] How Much for a Sherwood SE-3 ??!!! - HOLY COW

I think the sync-AM detector in the Flex Radio PowerSDR software is pretty good although I have not made any measurements. Just get a fixed frequency Softrock40 receiver board kit around 20 dollars and then run the stereo sound into a computer sound input and install the free PowerSDR software and you have a pretty good IF demodulator for just about any mode.

From: Tisha Hayes <tisha.hayes@gmail.com>
Subject: [R-390] SE-3 like functionality

If you break the SE-3 down into the basics it has a good PLL, filtering and audio amp. All of those elements have been well documented for several decades (with solid state devices). The SE-3 is very nice in that it is a single solution pulling together all of those things into one package. It would not be difficult to design an equivalent product. You could do much more with an SDR device attached to the IF output of the receiver where you could let processing power down-convert, demodulate, filter, etc...

From: frank hughes <fsh396ss@gmail.com>
Subject: [R-390] Sherwood

One of the interesting things Rob mentioned to me when I bought an SE-3 years ago was component availability. The issue was difficulty obtaining some of the components that the design required, sounded like there were some items being discontinued that he needed. Must be a pain to keep a design going and avoid having to re-design just to keep up with component availability.

Date: Sun, 20 Oct 2013 10:25:10 -0400
From: Bob Camp <ham@kb8tq.com>

Subject: Re: [R-390] Sherwood

Which is why you probably should re-design it with up to date parts if you wanted to keep selling them. SMT has pretty much taken over in the world of semiconductors. There are some parts (or even categories of parts) that simply are not available in a "hand solder" sort of package. Yes for a home build you can find this and that. For a commercial product that's expected to last, off to the pick and place machine ?.

None of this is a knock on the fine design job he did on the SE-3, it's just the way the semiconductor business has gone over the last two decades. I doubt that we have done a single "non SMT" design at work in the last 10 years. We've probably done several thousand SMT designs. Just to be clear - to me SMT is anything that is fine enough pitch that hand solder is not economically practical. By that definition a SOT-23 is not a hand solder part (yes I've been hand soldering them since the 1970's) in a deliverable product.

Subject: [R-390] Sync Det II

The ski that Al sent me from the QST is the one I was thinking about and I started re-drawing it with photoshop elements as a bit image. Several hours down the road working on the schematic I decided to see what IC's were used. Then I discovered a major problem. They all seem to be "unobtainium". The one source listed is out of business. My search on Ebay didn't show anything except two surface mount NE602 pieces. I didn't follow up on the IF subsystem that was used for availability.

Unless someone has sources for these IC's this becomes a dead end project unless some on the list is able to redesign it with available components. Redesigning it is far beyond my skills.

The project needs two NE602 and one NE604 FM IF subsystem IC's. If anyone wants to search them out and they are available at a somewhat reasonable price the list would appreciate the info.

From: Perry Sandeen <sandeenpa@yahoo.com>
Subject: [R-390] Sync Det III

The hunt continues! I had to reformat this message removing most of the prices as the reflector list spam filter rejected it as looking like spam. Thanks to a tip from Sam Letzring and others I learned that the needed IC's are sort of available with the SA prefix. One problem will be that most of the parts supplies carry the SOIC versions but I found a few exceptions.

What I found: Newark: They can get the IC's from England but they are pricey. Newark also carries a SOIC 16 to DIP 16 ARIES-16-350000-11-RC - IC ADAPTER, 16-SOIC TO 16-DIP. The prices are much larger than DigiKey and Mouser.

Mouser: Mouser Part #: 771-SA602AN/01 Description: RF Mixer LP VHF DBL-BAL W/OSC

Mouser Part #: 771-SA604AD01112
Manufacturer Part#: SA604AD/01,112

Digikey: 68-1202-5-ND. SA604AD/01,112
NXP Semiconductors IC FM IF SYSTEM LOW PWR 16-SOIC
68-1200-1-ND SA602AD/01,118
NXP Semiconductors IC MIXER 500MHZ UP CONVRT 8-SOIC
Ebay Stores hifiic: SA604N 16 pin DIP High performance low power FM IF

system

Heinz Breuer found these two DIP parts:
221134875281 PHILIPS NE602AN DOUBLEBALANCED MIXER
AND OSCILLATOR 320995189811 SIGNETIC / PHI DIP, Single Radio
Communication IF Amplifier, NE604AN

I'm going to search some more based on Todd finding some for \$42/100

I'm in the process of redrawing the original schematic with photoshop elements into a bit image that can be reproduced in any size W/O smearing. I'll make a posting on the list when I'm finished and will email it to any interested. A bit further down the track I'd like to get a PC board made using through hole components. I have nothing against the new stuff but it is so small that it is too hard for me to use.

Subject: [R-390] SSB for the R-390A

Feeling a bit adventurous after adding the Treetops Circuits SSB module to my R-390A, I felt that using the pair of BFO xtals I had would be a useful addition for selecting either sideband as well as using the inbuilt BFO in the receiver. The accompanying photos and circuit description -in the pdf tells the story of adding the switchable xtal and interconnections. Non of the alterations involve major circuit changes and completely reversible. I'm happy to supply any words of encouragement and /or clarification as required.

Subject: Re: [R-390] SSB for the R-390A

Pictures got stripped off somewhere along the way.

One of the gotcha?s with SSB on the 390 is the way the filters are set up. USB isn't the same for any two filters. These days a cheap little DDS chip would take care of that pretty quick. With crystals, you have a lot of them to cover every combination (some of which admittedly aren't much use). Fixed injection frequencies do make things a bit easier no matter how you do it.

Subject: Re: [R-390] CV157 manual

Roy, sorry to hear you are sick. Let me reinforce your message.

I had a CV-157 for a time. The madman who sent it to me sent it in a box for paper towels filled with peanuts. The 100 KC section looked like something heavy had fallen on it, and I never got it working.

The problem with bringing it up on a Variac is that the rectifiers are thermionic. No DC will flow until the heaters are at red heat, near 85% of rated line volts. They heat up rapidly and soon put full voltage on the caps. The best thing to do is to use an external DC supply on only the main filter caps. You have to isolate those caps.

The next best thing to do is to put a lamp socket in series with the line, assuming you still have incandescent lamps in 60, 100, and 150 watt sizes. This will save the transformer and regulate current to the caps. Now, 60 watts may not let a beast like the 157 warm up, so you'll need to try higher wattages until B+ starts rising. Maybe even parallel lamps.

Don't pull all of the tubes. There are lower voltage electrolytics that will get full B+ if the tubes aren't there to load the circuits.

That said, this is military gear, not commercial. It would probably come right up. A big light bulb in series will serve to protect the transformer from overloads. A bright bulb means trouble. And if all you want to do is protect the transformer, then a fuse of the proper rating will do that. I've seen gear with a copper tube where the fuse used to be.

What will you use to test the functionality of the 100 KC auto tuner?

Subject: [R-390] another CV 157 question

Anyone happen to know how many CV157s were built? My serial numbers ranges

are between high 70's and low 130's.

I have NOT got one of the 157's up working yet and with my present back log of 390 and 390A work, it will be at least another week before I have a free bench. However, from my limited understanding of the 157 so far.. I am not too impressed. It has a vernier tuning control but no additional filters nor tunable BFO or notch filter.. Again, I am new to these beast and maybe I'll be more impressed soon; sure hope so!!

On the first unit, I am going to rebuilt the PS before going forward. These are just too rare to take chances with.. Trust me, I will make as sure as humanly possible to have stable power before pulling the mains.trigger. We need NOT to get into a big discussion on this!

On the other hand, I have several Hammarlund HC10's and have been very pleased with them. The vernier tuning is very nice for CW or touching up any signal that may have drifted. The HC 10 also has it's own filtering which is post R390 and (A) filtering as well as a tunable BFO and notch filter that work well. The audio from the HC10 is decent and better than a stock R390A.. The only issue with the HC10's is they are also rare and now fetching \$800 or more on epay..

From: "Bill Hawkins" <bill@iaxs.net>
Subject: Re: [R-390] CV-157 SSB converter

That's a good source, Norm. The manual says the 157 was designed to recover both upper and lower sidebands. It does not clearly state that these are sidebands of a suppressed 100 KC carrier.

*** Has anybody used one of these on the SSB signals available today?

As the manual says, the 157 was designed to provide the equivalent of two multiplexed telephone lines to channels A and B. Maybe a channel can deliver a plain telephone voice signal. Really don't know if it works without the 100 KC carrier. The control labeled AFC that looks like a circle with two dots on it is actually a disk driven by a motor shaft that turns a variable capacitor that trims the local 100 KC oscillator to match the received 100 KC suppressed carrier. Like so much of what Collins did, it was the peak of what you could do with vacuum tube technology at the time.

From: John Vendely <jvendely@cfl.rr.com>
Subject: Re: [R-390] CV-157 SSB converter

The CV-157 demodulates fully suppressed carrier signals just fine with AFC switched OFF--but with one serious drawback (relative to other converters). Its 555 kc LO, which is motor driven in AFC mode, is inherently much less stable than the oscillators in the companion R-390(*) receiver, and the entire receiving system's frequency stability is somewhat degraded as a result. This is particularly true during the first half hour or so of warmup. The CV-157 was really designed for pilot carrier AFC operation, with the transmitter's carrier level typically reduced 16-20 dB below PEP. In AFC mode, the drift was relatively insignificant.

In the early 1960s when synthesized equipment began to proliferate, there was a big incentive to get rid of the wasteful pilot carrier and reallocate its power to additional sideband intelligence, and the stability problem became an issue. The solution was the Manson Laboratories SBM-1 "Stabilization Kit" designed as an upgrade for the R-390A and CV-157. A number of AN/FRR-41 systems were retrofitted with it, especially by the Air Force. The system consisted of the Model 299 Synthesizer, which provided a synthesized 2.455-3.455 in 100 cps steps for both 390As, and the Model 372 Stabilizer, which synthesized all the crystal injection points for the two R-390As, plus a synthesized 555 kc and 100 kc for the two CV-157s. The FRR-41, thus modified, could be then operated either fully

synthesized, or with continuous tuning and pilot carrier AFC as originally, . I have one of these updated FRR-41 systems, and it works great, although the synthesizers are quite cranky and require frequent attention. The system I have was used by the 45th Space Wing as an ISB high speed computer data link on the Eastern Test Range in the mid 1960s. This may have been the world's first computer wide area network--and on HF! Later, the enormous remotely-tuned DDR-506 receivers, developed by TMC, were used for similar purpose by NASA between NASA Goddard, Wallops, and the Range & Instrumentation ships during Project Apollo.

But back to the CV-157. Other than the matter of stability, it's a great piece of gear when it's working and properly aligned (which is a bit of a chore). The main problems seem to be failed crystal filters (usually LSB, for some reason), and failed power transformers (usually the high current filament winding). Some crystal filters have aged badly and have poor response, though they haven't failed altogether. Carrier level meters tend to fail frequently, for some reason. Of course, you have to reform all those electrolytics and replace a buncha toobs. But when you're done, you'll have a marvelous piece of equipment.

BTW, a common misconception is that the CV-157 is a Collins design, a natural assumption given its obvious R-390-like appearance. It was actually designed by Hoffman Laboratories in the early 1950s, based on a patent they held. Three companies seem to have made them, Hoffman (early units), Dubrow Electronic Industries (late 1950s), and Bridge Electronics. Bridge seems to have made the largest quantity, on a 1962 contract. Collins never made any. I don't know how many were made, although it was obviously a tiny fraction of the number of R-390/390As produced. Please keep us all informed of your adventures as you dig into those CV-157s!

Subject: Re: [R-390] Sp-600 Product Detector

Here is a product detector circuit using an LM1496

<http://www.electronic.net/radio-frequency/product-detector-using-lm1496.html>

There was a construction article in Electric Radio magazine sometime back in the 1990s by Bill Klermos(sp) I built it and it works good. You must hit the chip with low Z signals. As I remember, the bfo amp tube converts to a cathode follower then injects the beat osc signal. The IF output is already a cathode follower to a connector on back of the chassis. The chip doesn't like too much signal, therefore a pot is inserted in each input for adjustment. The sp600 AM detector remains intact and a spdt toggle switch selects either the AM detector or SSB product detector.

Subject: [R-390] R-390A 6BE6 Product Detector changed to 6BY6

I made the Capt. P. H. Lee 6BE6 product detector change to one of my 390As about 15 years ago. After making some minor adjustments to it and installing the Dr. Langford 2 diode AGC change, I've been very happy with it. I recently improved the S/N of the RF and IF decks, but it seems like there is still too much tube noise. When I converted it to a product detector, the noise level went down 2 db from using the BFO and diode detector, but when I turn the product detector on, the noise is still 2 db more than without. When I did the conversion, I paid close attention that the audio level would be the same when switching between SSB and AM.

When I did the change, I thought that the signal levels would be high enough, that a low noise tube would not make any difference. Well, that was a bad assumption. I started looking for a low noise alternative, and found a few: 6BY6, 6CS6, quieter 6BE6, and others. I had more of these tubes, so I started with them. I did not make any circuit changes and tried them. I found a quieter 6BE6, 1 db. The only 6CS6 I had was also 1 db quieter, but the oscillator output was down 3 %. Not a big issue. I tried the 6BY6, and it was 2 db quieter, had the same oscillator output, and the same audio output, and the noise level is now the same in SSB or AM. I don't have any spare time to look for a better solution, so 6BY6 it is.

Subject: [R-390] R-390/R-390A AGC for SSB, fix to Dr. Lankford's 2 diode mod

I added a product detector to my R-390A daily driver many years ago - thank you Capt. P.H. Lee. Worked great, but the AGC was not good for SSB. When I heard of Dr. D Lankford's 2 diode mod, I tried it right away, and it worked great. Thank you Dallas! SSB is now great. But, it did remove the 'delay' in the AGC. I was not aware of it right away, but did notice some side affects:

1. Weak signals did not come in as well as before.
2. Audio output was reduced.
3. Noise limiter did not work quite as well.

I had a good idea what the AGC was supposed to do, but could not find any measurements anywhere, so I took a few measurements without the mod on, so I could see what it was suppose to do on weak signals:

| uv in balanced | AGC det pin 1 V | AGC TB102 p3 V |
|----------------|-----------------|----------------|
| 0 | -0.4 | -.15 |
| .5 | -1.7 | -.18 |
| 1 | -3.2 | -.23 |
| 2 | -4.9 | -.65 |
| 3 | -7.6 | -1.25 |
| 4 | -9.2 | -1.6 |
| 5 | -11.1 | -1.9 |
| 10 | -15.2 | -3.2 |
| 20 | -17.4 | -3.6 |

It looks like the delay is overcome at about -3.5 V. It took me a little while to put it all together and even longer to come up with a fix. I wanted something simple and easy to remove. I finally decided on the following circuit: https://s26.postimg.org/hvmo7yhzd/IMG_7794s.jpg

After reinstalling Dr. Lankford's mod and my fix, I took the following readings:

| uv in balanced | AGC det pin 1 V | AGC TB102 p3 V |
|----------------|-----------------|----------------|
| 0 | -0.4 | -.15 |
| .5 | -1.6 | -.18 |
| 1 | -3.0 | -.25 |
| 2 | -4.8 | -.7 |
| 3 | -7.4 | -1.3 |
| 4 | -9.0 | -1.7 |
| 5 | -10.8 | -2.0 |
| 10 | -15.0 | -3.3 |
| 20 | -17.0 | -3.7 |

As can be seen, the AGC voltages are very similar and it is working very well for

weak and strong SSB, CW and AM signals.

From: "Gary I. Biasini" <gary.biasini@shaw.ca>
Subject: [R-390] R-290a modified IF sub-chassis

Good Day. This is my first post as a member so I hope I don't run afoul of any of the rules which I have carefully read. I recently purchased what purports to be a Teledyne Systems R-390a Serial number 2697. I say "purports to be" because the various sub-chassis are as follows:

RF sub-chassis -

Capehart Corporation Order No. 21582-PC-61, Serial no. 585

Crystal Oscillator sub-chassis -

Capehart Corporation Order No. 21582-PC-61, Serial no. 626

IF sub-chassis -

Capehart Corporation Order No. 21582-PC-61, #808

Power Supply sub-chassis -

Capehart Corporation Order No. 21582-PC-61-A1-A1, Serial no. 713 Audio sub-chassis -

Teledyne Systems Corp. Order No. 37856-PC-63

PTO - Progressitron Corp. Type 798 Serial No. 8703

I purchased the receiver from William Pearl, a formerly licensed ham operator living in the Long Beach, CA area. I happened to be in the Phoenix AZ area at the time I agreed to purchase it so my wife and I drove out to meet Bill and pick up the receiver in person.

Bill advised that he obtained the receiver more than 30 years ago from another ham and, after children arrived, it sat in his garage unused for 30 years. He said he turned it on prior to selling it and, with a short wire antenna, it picked up some stations.

I have carefully read the admonitions against turning on the receiver until a few things are checked out and replaced like C553 and, have ordered replacement caps for all of the paper capacitors and others that are recommended and will hopefully find time to replace them in the next few months. In the meantime, in looking at the receiver, it appears that a number of modifications were made, some of which I cannot seem to find in the archives.

This first message will discuss the modifications that I have noted on the IF sub-chassis. In particular, I note a 1,000 uF 25VDC electrolytic capacitor and an unknown device with 8 leads exiting the body. I assume that this is some sort of AGC modification. Any comments would be welcome and any questions will be answered to my ability.

The URLs to pictures of the modified module are below:

From: "Gary I. Biasini" <gary.biasini@shaw.ca>
Subject: Re: [R-390] R-290a modified IF sub-chassis

Thanks to all who have responded. I have now had the opportunity to trace the circuit. It appears to be a partial implementation of the Capt. Paul H. Lee product detector modification. Referring to the R-390a 2K manual description (Chapter 11, pages 31 following):

1. There are no modifications to the panel wiring, so , steps 3 - 13 are not performed;
2. Steps 15 and 16 appear to have been performed;

3. Step 17 is 10K resistor not 11K;
4. Steps 18 to 20 appear to have been performed;
5. Step 21 was not performed;
6. Step 22 appears to have been performed;
7. Steps 23 and 24 are not performed presumably per suggestion of Eugene A. Hubbell, W7DI;
8. Step 25 appears to have been performed;
9. Step 26 is a 1,000 uF 25VDC electrolytic rather than 63VDC as prescribed;
10. Instead of an insulated standoff per step 27, pin 4 of RT510 was used;
11. Step 28 is a 27K resistor;
12. Steps 29 and 30 are not performed;
13. Step 33 (replacement tube 6BE6) is installed;

The link below is my rendition of the schematic including the mystery 8 pin part previously advised of. Again, any suggestion as to what this modification accomplishes would be appreciated.

From: Larry H <dinlarh@att.net>
Subject: Re: [R-390] R-390a modified IF sub-chassis

Gary, Capt. Lee's implementation switched the audio after the noise limiter stage. This is very similar to his original except it switches the audio before the limiter, thus providing noise limiting in SSB mode. In AM mode, the required bias is provided to the limiter circuit through the negative diode load voltage. However, in SSB mode an alternative method must be provided. There are 2 pieces in this schematic. Part of it is from the rectified 25.2 vac creating a fixed negative voltage. The second and variable part is that provided by the mystery module, obtaining its input from the diode load voltage. In theory this would work, but I have no way of knowing. If it were mine, I'd try it and see. Remember, with this mod on, this IF is not interchangeable with other R-390A's.

Date: Thu, 28 Sep 2017 09:20:50 -0400

From: "Jacques Fortin" <jacques.f@videotron.ca>
Subject: Re: [R-390] R-390a modified IF sub-chassis

I believe that the "mysterious module" is a reed relay. The coil should be activated thru the 33k, 2W when the BFO power is on and the relay contacts exchange the AM detector and the SSB product detector outputs going to the limiter stage. Something is still not clear with the schematic provided by Gary, because it cannot be seen how the AM or SSB audio goes to the limiter input... ?? Anyways... using a relay there prevent the mainframe/IF module wiring changes to carry the AM detector and SSB demodulator outputs to the front panel to be selected, as well as the required change of S101. In other words, using a relay within the IF module makes the modified/unmodified IF modules interchangeable within the R-390A "stock" mainframes. I implemented something similar in my own R-390/390A by using a small relay with a 24V coil (coil resistance 1.8 - 2.0k) connected in place of R531.

As we are there, using a 1000uF to develop the - DC bias source is overkill: a 100uF @ 40-50V is way sufficient. If anyone still fears to introduce "hum" in the audio in SSB mode that way, a small negative 24V regulator (or more simply a Zener) can be used there.

Subject: Re: [R-390] Product detector

Alex, nice unit. Major advantages of your unit is no R-390A mods, you provide AGC to the R-390A, and you use the R-390A audio. I like that you are feeding the audio out of your SSB unit back into the R-390A noise limiter input on contact 15. There is one issue though. In order for the R-390A noise limiter to work correctly, it requires a negative bias in relation to the received signal strength. In AM mode this is provided by the diode load signal. But it should work fine with the N/L turned off. If you wanted to use the n/l, you could add an agc derived bias to the audio out.

Subject: Re: [R-390] Product detector

What if we let the AM detector output connected to the limiter control (R120, term 3) at all times, but we feed the output of the SSB demodulator to R527 In my implementation of the Cap't Lee modification, I have put the relay changeover contact directly to R527. In AM, R527 is then connected to J512-3 (like in a non-modified IF deck) and in SSB (BFO powered) R527 is connected to the 200pF 2nd filter cap that was going originally to the BFO "double" sw by using J512-1 in

Cap't Lee article. I do not use a supplementary negative voltage generator (the 1000 μ F and diode connected to the 25.2V and etc.)

In your opinion, does the negative voltage produced by the AM demodulator alone can be sufficient for the limiter when SSB signals will be received ? What about also changing the R527 value to 62k ? I remember having read something about to reduce the limiter stage distortion.

Subject: Re: [R-390] Product detector

Your 1st Q:

What if we let the AM detector output connected to the limiter control (R120, term 3) at all times, but we feed the output of the SSB demodulator to R527 ?

A: That would work if the bias out when receiving ssb were high enough, but it's only a 1/4 of what is needed.

Your 2nd Q:

In your opinion, does the negative voltage produced by the AM demodulator alone can be sufficient for the limiter when SSB signals will be received ?

A: Unfortunately, no. The limiter bias needs to be 2x the peak of the audio input. This level is important for the limiter to work correctly. Too low = distortion, too hi = impaired limiting.

Your 3rd Q:

What about also changing the R527 value to 62k ?

A: This will just reduce the level of the audio in to the limiter. This will cause reduced fidelity out of the limiter due to the signal level being too low for it's design.

Your 4th Q: I remember having read something about to reduce the limiter stage distortion.

A: Yes, the bias on the limiter needs to be increased a little bit (about 1.4v) from the original design. I added a 2.4 k res between S108B #7 and the junction of resistors R532, 533, & 534. I only did this mod after verifying my limiter components were all working correctly. It did work correctly before, except on strong AM stations. And, I have seen a slight improvement in sound quality on all signal levels.

Subject: Re: [R-390] Product detector

Hi Spence, If you are referring to the link in here, then that was from Alex. I do like the schematic, but you'll need to ask him about it. And yes, Alex's external ssb adapter that connects to the R-390A should connect and work with the R-390 just fine.

From: Gordon Hayward <ghayward@uoguelph.ca>
Subject: [R-390] External product detector

I built an external product detector with 2 MC1496 mixers. The crystal BFOs are for USB, LSB and one exactly at 455 kHz for zero beating AM stations. The BFOs are fed to the two detectors in quadrature (90 degrees apart) which are fed to right and left channels. The stereo effect on the noise is remarkable.

I also added a PLL FM detector and a precision diode detector for AM just because I could. I don't use them much. The box also includes a logarithmic voltmeter as a second S-meter for low signals.

A third addition was a CL-90 thermistor to slow start the 390A.

Subject: Re: [R-390] External product detector

There are a number of < \$50 and some <\$20 MCU boards that will make a fine SDR for single frequency use. Yes, I realize this is heresy. If you are going to add solid state stuff to an R-390 anyway. why not do it the best way you can? IF comes out here, goes into board, audio comes out of board there, goes back into radio here. for added bonus points, AGC comes out of board there and goes back into radio over here.

Subject: Re: [R-390] Internal Product Detector

Out the 455 KHz on the back panel. Through your surplus selective volt meter.
Wire the volt meter output back into the diode load after you remove the jumper.
Get some levels adjusted and you would think you were listening to a rice box of
its era. The Collins Engineers knew these options were in the coming technology
and built the external back panel connectors into the original chassis frames.

Hang a diode on the 455Khz output and couple that back into the diode load.
Begin improving on your detector circuit. You know what is going into the
circuit. You know what needs to come out of the circuit to drive the R390 audio
circuits.

Make the solution general. A 455 Khz IF input and an audio line load level out put
and a good 2 watt audio amp.

A couple good off the shelf options have been suggested in the other contributions
to this thread. It plugs in, it is reversible, no one goes insane when hearing
another boat anchor has been so violated.

Subject: [R-390] my experiences with internal product detectors

My personal preference is for an internally mounted device. If you are happy with
having a separate box that is external to the receiver then you have lots of
options, starting with a cv-157 or a cv-591a, which is of course the opposite of
an internally mounted device.

My first experience with an internal modification was the lee product detector
from cq magazine in 1961. this product detector worked well. however, it did not
address the agc issue, so when i was done, overall performance was poor. the lee
modification is straightforward, but its not the sort of thing you can perform in
an hour.

my second attempt at a product detector appears at pp. 42-45 of the august, 1974

issue of 73 magazine. it is merely a rewiring of the existing detector and limiter tube sockets and associated components. this modification was ok on cw and ssb, but not good on am and the limiter was no longer useful, which i keenly missed on 80m cw.

the last device i tried was the jan skirrow detector, which is a fine performer, but suffered from several shortcomings, some of which are just my own personal preferences. first, while the board is small enough to fit within the r-390a cabinet, it is not small enough to fit within the intermediate frequency module itself. second, the user must make several critical level adjustments via on board potentiometers. third, the agc circuit is unmodified and the recommended operating procedure is to bypass the agc circuit and use the rf gain control as a volume control. i want to emphasize that it nonetheless works well when properly adjusted.

the device i received from the 1u2u.net site included the components and instructions for adding a simplified (and improved) lankford agc circuit, as well as the product detector board itself, so that was a definite plus if you are starting with a stock receiver. the board fits entirely within the intermediate frequency module. it saved a lot of time and it resulted in a complete solution (product detector/agc/bfo).

Subject: Re: [R-390] my experiences with internal product detectors

The problem with an internal product detector is that it is simply the first step in a very long series of steps. You hack in the detector and get it feed back into the audio system. Now the AGC really isn't right so you start hacking it. SSB AGC isn't as easy as it seems so it's a bit of work. Next you decide you want SSB noise limiting. That makes the AGC stuff seem like a cake walk.

At this point we're done and it's time for beer and your favorite sausage on the grill right? Not so fast. There's the pesky issue of selectivity and you really wanted at least one notch filter didn't you?

It just goes on and on.

Subject: Re: [R-390] my experiences with internal product detectors

I've pretty happy using the CV-591A converters. They work well and really are not that large, after all the R-390a is not a compact receiver. The choice of manual or crystal sideband slicing is nice and with the BFO off it offers selective sideband AM. Never have been able to find a CV-157, they seem to be as unobtainium (maybe more so...)as a R-389 <sigh>.

There were some R-390A's converted for Mexico that had built in SSB capability. I don't remember all the details and have only seen one on ebay and another at Dayton long ago.

Subject: [R-390] Kahn CV 1982 TSC 26 Product Detector

I recently acquired a very rare Kahn CV 1982 / TSC 26 product detector made for 455 - 500 KHz IF's. This is an amazing unit made up primarily of NuVistors, 24 as I recall. It came with what looks like a copy of a copy of the manual with a number of poor quality pages and a good bit of info which is not legible. I am in the process of checking the ESR on the electrolytics and most are decent except the canned units which read high. My question is, does anyone have an original manual that I could rent, buy, beg or borrow for a week. I have access to a copy shop which can do a high res copy in a few days. If someone can help me with this, I will make a copy for them in addition to a fee for the manual's brief usage and postage both ways. I will also send it back via priority mail.
